ALIGANJ HOUSING SCHEME
LUCKNOW-226 020CERTIFICATE

This is to certify that Mrs. Kanchan Singh has worked under my supervision for her thesis entitled "Sources of Economic Growth in Uttar Pradesh" being submitted to the Kanpur University for the award of the Ph.D. degree in Economics.

I further certify that :

- (a) the thesis embodies the work of Mrs Kanchan Singh herself;
- (b) Mrs. Kanchan Singh has put in over 200 days attendance in the Giri Institute of Development Studies, Lucknow as required by Ordinance 9 of Kanpur University.

T.S. PAPOLA
Research Supervisor

August 29, 1987

Forwarded
B.A. Jais

CERTIFICATE

This is to certify that the work embodied in this thesis entitled "SOURCES OF ECONOMIC GROWTH IN UTTAR PRADESH" is an original work done by me. I have prosecuted research towards the submission of this work on an ICSSR Doctoral Fellowship for the period of about four and half years at the Giri Institute of Development Studies, Lucknow.

This work, being submitted to the Kanpur University, Kanpur for the consideration of the award of Doctor of Philosophy in Economics has not been submitted whether in whole or in a part thereof elsewhere for the consideration of any degree.

(MRS) KANCHAN SINGH

PREFACE

Economic growth depends on the growth of basic inputs — land, labour, capital and in their combined efficiency or productivity. However, due to constraints on the increase in basic inputs, especially land, it becomes necessary that efforts be made to raise the combined efficiency of basic inputs. Therefore a study on measuring the contributions of various sources of growth and assessing their relative importance in the growth process of the economy assumes vital importance.

On the macro-level, very few studies are available for the country and none so far at the regional level. However, the vastness of the country and widely diverging growth experiences of the regional economies within it require that such studies be carried out at the regional levels. The present study entitled "Sources of Economic Growth in Uttar Pradesh" is an initiative experimental exercise in this direction.

I am grateful to the Indian Council of Social Science Research, New Delhi for giving me the opportunity to work as a full time research fellow under the salary protection scheme at the Giri Institute of Development Studies, Lucknow.

I would like to express my deep sense of gratitude to my research supervisor Dr. T.S. Papola former Director GIDS, Lucknow, for the advice, guidance and encouragement that I received from him throughout. His keen interest in this study was a constant source of inspiration to me.

In the course of the study I have received help and assistance from a number of persons. While it is not possible to mention them all individually, I would be failing in my duty if I do not recognize the help and support I have received from several persons at GIDS. I would particularly like to record my thanks to Dr. M.S. Ashraf for his cooperation and support at various time, and to Mr. R.C. Sinha and Dr. R.T. Tewari who have been generous with their time and have always been ready to discuss problems and issues relating to this work.

I would like to express my appreciation for the ready help and assistance extended by the Librarian and Staff of GIDS, Lucknow, the Economics & Statistics Library, Lucknow, the C.S.O. Library, New Delhi and the Economics and Statistics Library, New Delhi.

To my friends at GIDS I am extremely thankful for the assistance rendered by them. My thanks are due to Shri N.B. Bhatt who efficiently undertook the typing of the manuscript.

Lastly, I take the opportunity to thank my family members for forbearance and cooperation that has been given to me at all times.

KANCHAN SINGH

Chapter 1

INTRODUCTION

1. Background : A Look Back at Earlier Studies

What sources lead to the growth of output in the long-run? Is the relationship between aggregate output and the sources of its growth essentially a technical one? These are some of the issues that seem to have created enough unrest in the minds of economic theorists since long. In their quest to resolve some of these issues, economists discovered land, labour, capital and also technical change as the proximate sources of growth of real output. However, relative importance which they placed on each of these sources, or group of sources, has varied from time to time.

Early economists believed that growth of real output was primarily a function of growth in quantities of inputs. It does not mean however, that these economists were unfamiliar with the concept of technical change. Adam Smith was quick in noting the importance of this factor.¹ He distinguished both labour saving

¹A. Smith, An Inquiry into the Nature and Causes of the Wealth of Nations, E. Cannan (ed.), 1937, Chapter I, pp.3-12.

and capital saving technological changes. Smith was of the view that these changes occur through the invention and application of improved machinery and division of labour and increase the per capita income by enabling one man to do the job of many.² Technical change was not ignored by Ricardo. He, however did not believe that these changes could be powerful enough to prevent the operation of law of diminishing returns. Instead, he believed that output growth could proceed only through the growth in capital accumulation, and as latter was sure to cease due to the declining tendency in the rate of profit, increase in real output could not continue indefinitely.³ Marx

²A. Smith, op. cit, p.7.

³D. Ricardo, On the Principles of Political Economy and Taxation, 3rd edition reprint, E.C.K. Gonner (ed.), 1981, pp.272-284.

For Ricardo's views on economic progress and technological change, see :

iii) P.R. Brahmananda, Productivity in the Indian Economy : Rising Inputs for Falling Outputs, Himalaya Publishing House, 1982, pp.14-15.

while noting the importance of technological change as a prime mover in the development of a capitalist economy,⁴ ended with similar pessimism about the prospects for future economic growth. Thus, while these economists took cognisance of technological change as an important factor in economic growth they failed to appraise its powerful effect on output growth in the long-run. This is because they believed that such changes occur very gradually, causing only a temporary disturbance in equilibrium.⁵

Neo-classical economists considered technological change as purely an exogeneous factor. They also under-emphasised its role because of their pre-occupation with static equilibrium analysis involving maximisation

⁵A. Heertje, op. cit., pp.35-36.

of output with optimum resource allocation.⁶ They failed to realise that "economic growth is, in many important respects, a learning process, a process where by the human factor acquires new skills, aptitudes, capabilities and aspirations. And a pattern of resource use which may maximise output from a given stock of resources may or may not generate the qualitative changes in the human agent which are most conducive to the growth of output in the subsequent time periods".⁷

Since the middle of the twentieth century a major change has occurred in economic ideas about the relative importance of increase in factor quantities and technological change in the process of economic growth. Empirical work, mostly for the economy of the United States, has shifted the emphasis from increase in factor quantities as a major source of output growth to technological change. J. Schmookler,⁸ F.C. Mills,⁹

S. Valavanis-vail,¹⁰ J.W. Kendrick,¹¹ M. Abramovitz,¹² and S. Fabricant¹³ are the protagonists of this view. Differences among them are no doubt there, but a broad conclusion emerging from their studies is that during 1869 to about 1955, only a small percentage increase in per capita real output in the United States could be explained as due to the increase in traditionally measured inputs viz. labour, capital and land; the unexplained residual growth being attributed to the contribution of technological change. Solow¹⁴ using the explicit assumption of an aggregate production function wherein technical change was measured as a shift, succeeded in establishing a theoretical base for measurement of sources of growth. Accordingly he showed

¹⁴R.M. Solow, "Technical Change and the Aggregate Production Function," Review of Economics and Statistics, Vol.39, No.3, Aug. 1957, pp.312-320.

that during 1904-1949 about 87½ per cent of the increase in per capita gross real output could be accounted for as the contribution of technological change.

After Solow,¹⁵ many attempts have been made to enrich this theoretical basis empirically and otherwise. Attempt has been to shorten the large residual which had remained unexplained in the earlier studies and inhibited the understanding of the sources of growth in the economy. Solow's¹⁶ own attempt has been important. He tried to achieve this objective by measuring the part of productivity growth or technical change embodied in capital. Denison made a distinct advance in this area in his 1962 work,¹⁷ further refining and updating it in his subsequent studies.¹⁸ He shortened the size of the

¹⁷E.F. Denison, Sources of Economic Growth in the United States and the Alternatives Before Us, Supplementary Paper No.13, Committee for Economic Development, New York, 1962.

¹⁸(1) E.F. Denison, Why Growth Rates Differ: Post-War Experience of Nine Western Countries, The Brookings Institution, Washington, 1967.

residual by ascribing a part of its growth to factor inputs, especially the labour, by measuring the effect of quality changes embodied in them. According to him, education, the main source of increased labour quality, contributed 23 per cent of the output growth in the United States during 1929-1957, which was more than the contribution of physical capital (15 per cent). The total factor input including quality change is estimated to have contributed 68 per cent of the growth of real income. The residual growth of 32 per cent has been further shortened by identifying and measuring a number of sources like economies of scale, resource allocation, shift of labour from agriculture to industry etc. Denison's final residual which he terms 'advances in knowledge' contributes only 20 per cent of growth.¹⁹ In his latter works he has identified and measured many other sources of growth like irregularities in the pressure of demand, fluctuations in farm output etc.

(ii) E.F. Denison, Accounting for the United States Sources of Economic Growth 1929-1969, The Brookings Institution, Washington, 1974.

(iii) E.F. Denison, Accounting for the Slower Economic Growth : The United States in the 1970's, The Brookings Institution, Washington, 1979.

¹⁹E.F. Denison, op. cit, 1962.

Others, after Denison, continued the analysis of the sources of growth further, by extending the list of previously identified and measured variables. Much of this effort has been on the lines of allocating more and more growth to traditional factors by developing more comprehensive measures for labour and capital input. Gallop and Jorgenson's²⁰ study uses the concept of a massive real input. Labour input in their study has been adjusted for changes in sex, age, occupation, education and the type of employment while capital input has been adjusted for six asset classes and three legal forms of organisations.²¹ Christenson, Cummings and Jorgenson²² make similar adjustment for measurement of real capital input.

²⁰Frank, M. Gallop and Dale, W. Jorgenson; "U.S. Productivity Growth by Industry, 1947-1973", New Developments in Productivity Measurement and Analysis, J.W. Kendrick and Beatrice N. Vaccara (eds.), Studies in Income and Wealth, Vol.44, NBER, 1980, pp.17-124.

²¹The Six Asset Classes are :

- i. Producers durable equipment,
- ii. Consumers durable equipment,
- iii. Residential structures,
- iv. Non-residential structures,
- v. Inventories, and
- vi. Land.

The legal forms of organisation are (i) Corporate business, (ii) Non-corporate business, and (iii) Household business.

²²L.R. Christenson, D. Cummings and D.W. Jorgenson, "Economic Growth, 1947-73 : An International Comparison" in Kendrick and Vaccara (eds.), *op. cit*, pp.595-691.

While these studies seek to narrow the residual by adjusting factor inputs for quality changes, others try to explain its size by making separate estimates of the sources making up the residual.²³

Though most of the empirical studies on the measurement of the sources of growth have been carried-out for developed economies, some break-through has been made in case of developing economies also. Quite in contrast to the developed economies, all these studies conclude that major source of economic growth is the increase in traditional factor inputs; technological change appears to have made relatively a small contribution.

Bruton²⁴ dealing with sources of growth in 5 Latin American countries estimated that during 1940-64, technical change contributed 25 per cent of the economic

²³Kendrick has estimated the effects of growth in intangible capital stock resulting from investment in health, education and training, research and development etc. in contributing to the growth of the residual. See, J.W. Kendrick, The Formation and Stock of Total Capital, NBER, New York, 1976.

²⁴H. Bruton, "Productivity Growth in Latin America," The American Economic Review, Vol.LVIII, No.5, December, 1967, pp.1099-1116.

growth in these countries. Gaathan's²⁵ study shows that in Israel during 1950-65, total factor quantity and total factor productivity, accounted for two-thirds, and one-third of the economic growth respectively. A cross-section study by S. Robinson²⁶ for 39 developing countries during 1958-66 revealed that 72 per cent of the measured growth was due to increase in labour and capital inputs. Of the remaining 28 per cent contributed by technical change, he estimated that 16 per cent was due to shift of resources from farm to non-farm activities.

Some other studies which count quality changes as a part of increase in factor quantity estimate still larger contributions of factor quantity and smaller contribution of technological change. Using such an approach Correa's²⁷ study for 9 developing countries

²⁵ A.L. Gaathan, "Economic Productivity in Israel, 1950-65," Review of Income and Wealth, Vol.16, No.1, March 1970, pp.1-18.

²⁶ S. Robinson, "Sources of Growth in Less-developed Countries : A Cross Section Study," The Quarterly Journal of Economics, Vol.LXXV, No.3, Aug. 1973, pp.391-408.

²⁷ Hector Correa, "Sources of Economic Growth in Latin America," The Southern Economic Journal, Vol.XXXVII, No.1, July 1970, pp.17-31.

reveals that increase in factor quantity and quality contributed about 50 to 94 per cent of growth of income in these countries. Maddison's²⁸ study relating to 22 developing countries shows that during 1950-65, growth of capital with an average contribution of 55 per cent was the most important source of output growth. Adjusting labour input for quality changes due to increase in levels of health, education and migration of labour from agriculture to industry, he estimates the contribution of labour input to be 35 per cent. Thus, 90 per cent of growth in his study turns out to be the contribution of labour and capital; remaining 10 per cent of being the contribution of technological change. Out of 22 developing countries, Maddison finds that five had negative residual growth due to decline in resource-efficiency.

A few studies on the measurement of sources of growth have been made specifically on India also. Applying basically the same methodology as used by Denison,

²⁸ A. Maddison, Economic Progress and Policy in Developing Countries, Allen and Unwin, London, 1970.

Dholakia²⁹ has estimated that during 1948-49 to 1968-69 total factor productivity in India grew at a rate of 0.92 per cent per annum, the technological change contributing 28.70 per cent of the growth of real output during the period. Bramhananda's³⁰ study shows that during 1950-51 to 1980-81 total factor productivity in India grew at an average compound rate of 1.16 per cent per annum, technological change contributing 32.86 per cent of the output growth.

2. The Present Study

While the macro studies for India mentioned above have their own significance, significantly varied growth experiences of regional economies within the large country, make it interesting to carry out such studies at regional or State levels. Such studies, if available for different states would not only throw greater light on the pattern of growth observed for the national economy, but would also enhance our knowledge about the causes of inter-state growth differentials. Since economic decisions to accelerate the pace of growth

²⁹G.H. Dholakia, Sources of Economic Growth in India, Goods Companion, Baroda, India, 1974.

³⁰P.R. Bramhananda, op. cit.

of any State including the decisions to mobilise resources for implementing various programmes (while guided by the broad objectives set at the national level) are taken mostly at the State level, it appears necessary to obtain a greater insight into the pattern of growth in the State economy and the relative contributions made by various sources to its past growth. Present study is a modest attempt in this direction.

The unit selected for the purpose of the study is Uttar Pradesh. U.P. with a population of 11.09 crores and an area of 29.4 lakh sq-km. accounts for 16 per cent of total population and 9 per cent of total area in the country. The population of the State has been increasing at an alarming rate. It has jumped from a rate of 1.8 per cent per annum during 1960-61 to 1970-71 to 2.3 per cent per annum during 1970-71 to 1980-81, which is higher even the national rate of growth of population.³¹ While important in terms of population and area, the State is among the most backward in the country. The State economy which largely stagnated

³¹Census of India 1981, Series-22, UP, Paper No.1 of 1981.

during the First Three Five Year Plans,³² started growing gradually thereafter, and, since the mid-seventies it seems to have picked up the momentum of growth.³³ Since 1974-75 growth rate has increased in all the three broad sectors primary, secondary and tertiary compared to the growth rates experienced during the earlier period since 1960. However, with population increasing at an alarming rate and very little prospects of increasing land area to be put into the productive use, reliance is to be placed on increasing use of capital. However, no significant improvement in the economic condition of the masses is likely to occur in the State unless resources are used more

³²(i) O.P. Gupta, "Rate of Economic Growth in Uttar Pradesh and Reasons for Its Retarded Development", in Economic Backwardness of Uttar Pradesh, paper read at the Seminar, Nov. 27-28, 1971, pp. 31-37.

³³A.K. Singh, "Uttar Pradesh Economy Poised for Rapid Growth", The Economic Times, Dec, 19, 1986.

productively. A quantitative appraisal of the relative contributions made by various sources including total factor productivity or technical change to the growth rate of output in the past could therefore, prove useful for this purpose.

3. Objectives and Methodology

Main objective of the present study is to measure the contributions of traditional factors viz., land, labour and capital, and also of the technical change in contributing to the economic growth of the State and its broad sectors, i.e., primary secondary and tertiary. It also seeks to assess their relative importance in contributing to the growth of the State economy and its broad sectors.

Towards the fulfilment of the central objective as stated above the present study has also to :

- i. measure the economic growth in the State economy during the reference period selected for the study.
- ii. obtain the functional break-up of State income among the primary factors land, labour and capital for the reference period.

- iii. measure the quantitative and qualitative growth of labour input in the State economy for the reference period.
- iv. measure the growth of capital and land inputs in the State for the same period as above.

Quantitative assessment of various sources for the economic growth of the State would be made following total factor productivity method in the neo-classical frame-work. The methodology assumes that growth rate of real output in the economy is composed of growth rate in total factor quantity and growth rate in total factor productivity.³⁴ However, the latter can not be measured as such and is obtained as residual after subtracting the rate of growth of total factor quantity from the growth rate of real output. Thus the crux of the method lies in computing a measure of total factor quantity and its rate of growth during the reference period.

The measure of total factor input or total factor quantity usually includes the traditional factors viz.,

³⁴The two terms 'technical change' and 'total factor productivity' are in fact not equivalent to each other. However, in conformity with the usual practice in empirical economic literature, these two would be used interchangeably in the study.

land, labour and capital. However, as these factors are measured in different units and grow at different rates over time, the measurement of aggregate growth of factor inputs is done by using index numbers of these inputs. Series of input indices are combined to obtain the index of total factor input. Percentage share of each factor in the net product is used as weight for aggregating the indices. Use of income share for this purpose assumes that marginal product of each factor is equal to its price, so that a one per cent increase in any input, keeping other inputs constant, results in increasing the total product by the percentage amount earned by that factor.

Growth rates of total factor input obtained from the combined input index when subtracted from the growth rate of real output would yield the rates of change of total factor productivity or technical change. Contributions of different inputs constituting the index of total factor input would be measured as the product of the growth rate of the input and its percentage share in output during the period. Various steps in the methodology are listed below :

1. Estimation of long-term rate of growth of the State economy, on the basis of time series of real income in the state over the reference period, that is twenty years from 1960-61 to 1980-81.
2. Obtaining functional distribution of State income into, labour, capital and land for the study period.
3. Construction of time-series of indices of factor inputs viz., labour, capital and land and estimation of average rate of growth of each during the study period.
4. Derivation of total factor input index as a weighted sum of the three traditional inputs, weights being the percentage shares of these inputs in net domestic product.
5. Estimation of contributions made by total factor input and its different constituents, and of total factor productivity or the technical change to the growth rate of real output.

Relative importance of total factor productivity in effecting the rate of growth of output would be measured in two ways - (1) treating technical progress

as purely disembodied i.e. without making any adjustment in factor inputs for qualitative changes, and (ii) treating it as partly embodied; by making adjustment for the quality of labour as effected by increased education and changing sex-composition among workers.

The present study proposes to undertake the sources of growth analysis in broad sectors also. Thus output, input, and total factor input indices would be prepared for three broad sectors viz., primary, secondary and tertiary.

4. Plan of the Study

The Chapter plan of the present study is as follows :

The present introductory chapter dealing with background, objectives and method of study is followed by the exercise in the measurement of economic growth in Uttar Pradesh (Chapter II). The main aspects of this exercise include the concept and methodology of State income estimation, trends in growth rate of real income during the reference period 1960-61 to 1980-81,

in aggregate and in the broad sectors : primary, secondary and tertiary.

Chapter III on Factor Incomes by Distributive Shares seeks to develop a set of weights for combining indices of factor inputs land, labour and capital. An exercise to prepare these estimates for major sectors of the State economy has also been undertaken. Growth of labour input in Uttar Pradesh is measured in Chapter IV. It attempts to develop an index of the growth of working force in U.P. after making adjustments to account for the definitional changes from Census to Census to make the data comparable. It also attempts to measure the qualitative growth in labour input due to increased education and changing sex-composition of the work force. Chapter V attempts the measurement of capital and land input in Uttar Pradesh during 1960-61 to 1980-81. After reviewing the problems in the measurement of real capital, an exercise has been made to build the capital input series for the primary, secondary and tertiary sectors and for the economy as a whole.

The major objective of the present study of measuring contribution of sources of growth is the subject matter of Chapter VI. The series of labour, capital and land prepared in earlier Chapters have been combined to develop the index of total factor input. Absolute and relative contributions of sources of growth have been measured using average growth rates of factor inputs, total factor input and real output. Similar exercise has been carried out for broad sectors also. The last Chapter (VII) summarises the main findings of the study and concludes by pointing out their implications relating to long term growth process and resource-use-efficiency in the State economy.

Chapter II

MEASUREMENT OF ECONOMIC GROWTH IN UTTAR PRADESH

1. Introduction

The measurement of economic growth should ideally mean an assessment of the long term productive capacity of the economy and not merely the trends in the current output. The increase in long term productive capacity or the productive potential is governed by the number of factors such as the growth of the working force, improvements in its quality, the stock of capital including natural resources available to the economy, accumulated stock of knowledge and aptitude of the society towards application of this knowledge.¹ A direct measurement of this productive capacity is not possible. It is, however, possible to measure it at least approximately, with the help of the actual output data stretching

¹E.F. Denison, Sources of Economic Growth in the United States and the Alternatives Before Us, Supplementary Paper No.13, Committee for Economic Development, New York, 1962, p.4. Also see Accounting for the United States Economic Growth, 1929-1969, The Brookings Institution, Washington, 1974, p.1.

over long periods by isolating the effects of short term fluctuations. These short term fluctuations and changes in intensity of resource-use associated with them are generally caused on account of two factors - (i) irregularities in the pressure of aggregate demand, and (ii) effect of natural phenomena like draughts, floods etc.² Of the two factors mentioned above, former is more important for industrially developed economies while latter plays a crucial role in under-developed agrarian economies where major part of output is derived from the agricultural sector.³

Real output data conventionally measured in terms of Real Net National Product or Real Gross National Product⁴ is used as a summary statistic for the purpose

⁴Here-after referred as Real NNP and GNP only.

of measuring growth of any nation or region.⁵ We have also adopted this procedure for measuring and analysing economic growth in the State of Uttar Pradesh, without going into the wider debate on the suitability and inadequacy of NNP or GNP as the true indicator of changes in the economy. Economic growth in the State has accordingly been measured with the help of State income estimates. Thus, before proceeding any further it would

be better to say a few words about the available income statistics in the State, its concept, and the methodology of its preparation.

2. State Income Estimates

The earliest attempt to estimate State income in the State was made by S.G. Tiwari.⁶ However, Tiwari's main objective was to measure the economic prosperity of the United Provinces (Under British India, Uttar Pradesh was called United Provinces). He estimated income of the United Provinces according to rural and urban sectors for three years namely 1921-22, 1931-32 and 1938-39. Baljit Singh⁷ also undertook an exercise to present the economic profile of Uttar Pradesh by making estimates of district incomes for the State. The estimates available from these studies are not usable for the present study as a growth accounting exercise requires series of income estimates for a fairly long period of time. However, Tiwari's study points out to the stagnating nature of the State economy during 1921-22 to 1938-39.

⁶ S.G. Tiwari, Economic Prosperity of the United Provinces, Asia Publishing House, Bombay, 1951.

⁷ Baljit Singh, Inter-district Incomes and Economic Profiles of Uttar Pradesh, Lucknow University, Lucknow, 1974, (Mimeo.).

Preparation of State income estimates at official level and on regular basis is a post-independence development. It was started in 1948-49 by the Economics and Statistics Division, State Planning Institute, U.P. We have three series of State income estimates prepared by the Directorate of Economics and Statistics, U.P.* The first series available covers the period from 1948-49 to 1960-61. The second series called the conventional series extends from 1960-61 to 1972-73. The third series referred as the revised series⁸ gives estimates from 1960-61 onwards, latest estimates being available are for 1985-86.

We could not get adequate information regarding coverage, source of data and the method of income estimation for the first series. Hence it has not been used for the purpose of the present study. Between the conventional and the revised series, there are wide variations in the coverage and sources of data. For example,

* Hereafter referred to as DES only.

⁸ Work on revised series began in 1967-68 following C.S.O's recommendation to all the States, to follow a uniform pattern of income estimation, so that, the estimates prepared by different States remain comparable to each other. See, Methodology of State Income Estimates of Uttar Pradesh (revised series), State Planning Institute, Economics and Statistics Division, U.P., Lucknow, January 1977, p.2.

classification of industries in the conventional series lacked the criteria of homogeneity of economic activity under different sectors, a drawback that has been removed in the revised series by a redistribution of economic activity in different sectors. For example, construction activity which was included under public administration in the conventional series has been accorded the status of a separate sector called "construction" in the revised series. The latter series incorporates improvements in the use of reliable and current data and also in the methods of estimation over the conventional series. Some of the important improvements are⁹ :

1. Net product from the agricultural sector at constant 1960-61 prices was estimated in the conventional series as the product of the gross value of the reference year at 1960-61 prices and the ratio between net and gross output as obtained in 1960-61. In the revised series, it is estimated by working out inputs of that year at 1960-61 prices and deducting it from the gross value at 1960-61 prices, during the year.

⁹Methodology of State Income Estimates (revised series), op. cit, p.3.

2. The method of estimation of income from the construction activity has been changed from 'income approach' in the conventional series to 'expenditure approach' in the revised series.

3. Income generated under the sector 'electricity gas and water supply' which in the conventional series was estimated on the basis of earnings per worker in the construction sector, is estimated in the revised series using the current information available from the annual accounts of State Electricity Board and Local Bodies.

4. Income from private mechanised transport, which in the absence of any data, was estimated in the conventional series, on the basis of per worker earnings in the private non-mechanised transport sector, is estimated in the revised series with the help of data available from various studies for this purpose, undertaken by DES.

5. For estimating income from the sector "other services", the conventional series adopted the procedure of projecting all-India average of income per person in the sub-sectors "other commerce and transport" and

"construction". However, in the revised series income from various services is worked out separately on the basis of data available from various rounds of National Sample Survey and latest data available from various departments and institutions.

6. The method of estimating income from the sub-sector "real estate and ownership of dwellings" has been improved in the revised series by using the information on number of residential houses given in the population Census and information of house rentals available from the Municipal Boards.

It thus appears that, not only the revised series is based on much improved sources of data and better methods of estimation compared to the conventional series, it also provides a longer time span for the purpose of the study. Hence the revised series would be used for the present study.

Having decided to use the revised series for the measurement of economic growth in the State we now proceed to examine the concept and methodology as adopted by DES in its preparation. This has been attempted

in the following section. The next section of this chapter deals with measurement of the growth of State income and presents an analysis of its behaviour and trends. The last section summarises main conclusions of the analysis and Appendix A given at the end of the chapter gives details of income estimation under different sectors.

3. Concept and Methodology of State Income

The Economic and Statistics Division, State Planning Institute, claims to follow broadly the same concept for State income as recommended by the National Income Committee and adopted by Central Statistical Organisation for preparing all-India estimates. The basic concept adopted for the final income estimates is that of Net State Domestic Product at factor cost (SDP) i.e., 'Income Originating' or the home produced income. Thus the State income may be defined as "the volume of goods and services produced during a given period within the geographical boundaries of the State in terms of money".¹⁰

p.1. ¹⁰Methodology of State Income Estimates, op. cit.,

No adjustment for inflow and outflow of goods and services across the State boundaries is made for the lack of relevant data. In this respect "the concept of State income does not strictly correspond to the concept of national income".¹¹

Adoption of the income originating concept though facilitates the computation of State income, it has the dis-advantage of making the estimates less reliable by introducing an element of arbitrariness in computing income from those activities which extend beyond the boundaries of the State like railway transport, banking and insurance etc. where direct estimation is not undertaken.¹² This is because "the institutional characteristics and nature of these sectors neither coincide nor can be usefully defined in terms of geographical boundaries of the State".¹³

¹¹V.D. Mahajan and D.N. Pitre, "An Operational Plan for the Improvement of State Income Estimates", The Journal of Income and Wealth, Vol.4, No.1, January 1980, p.12.

¹²V.V. Divatia, "On Computation of State Incomes" in Papers on National Income and Allied Topics, Vol.4, No.1, (Eds.) V.K.R.V. Rao, Sen, Divatia and Uma Dutta, Asia Publishing House, Bombay.

¹³V.D. Mahajan and D.N. Pitre, op. cit., p.13.

Further, the concept of State income being based on the 'income originating' approach, is less conducive for measuring the material welfare of the community in terms of increased goods and services which an index of income is usually conceived of as measuring.¹⁴ It thus "serves only as a measure of economic potential of the State".¹⁵

As at the national level, lack of requisite data prevents the exclusive use of any single method of computation.¹⁶ Hence all the three approaches namely product, income and expenditure have been used. For the activities extending beyond State territories like railways, State-wide allocation figures provided by C.S.O. are used.

For the purpose of income estimation all economic activities in the State have been grouped under thirteen major heads as given below :

1. Agriculture including animal husbandry

¹⁴See (i) S.G. Tiwari, op. cit., pp.37-39, and (ii) V.D. Mahajan and D.N. Pitre, op. cit., p.13.

¹⁵V.D. Mahajan and D.N. Pitre, op. cit., p.13.

¹⁶This part relies heavily on the Methodology of State Income (revised series), op. cit., pp.1-49.

2. Forestry and logging
3. Fishing
4. Mining and quarrying
5. Manufacturing (registered and unregistered)
6. Construction
7. Electricity, gas and water supply
8. Transport, storage and communication
9. Trade, hotels and restaurants
10. Banking and insurance
11. Real estate, ownership of dwellings and business services
12. Public administration
13. Other services

For each of the sub-sectors comprising the primary sector i.e. agriculture, forestry, fishery and mining*, production method is used. The method consists in first evaluating gross value of output at the producer's price and then subtracting from it the expenditures on

* However, for the purpose of this study mining sector has been included in the secondary sector instead of the primary sector.

cost items. Due allowance is made for trade and transport margin. To arrive at the figures of net value added, value of depreciation is also subtracted. Value figures in respect of most of the items in the primary sector are current and reliable. However, the cost figures are generally weak. This is because the primary sector is by and large an unorganised sector. Most of the activities under this sector are concentrated in rural areas. Production is generally carried-on on the household basis with the help of family labour, and is not very much geared by profit motive. This combined with illiteracy of the workers, results in the lack of any systematic record of cost incurred in carrying out the production. Hence information on cost items in this sector is rather scanty. Depreciation figures used are also those suggested by C.S.O. However, attempts are being made to obtain regular cost figures in respect of some important crops and other activities in this sector.

Production method is also used in case of registered manufacturing for which current and reliable data both on value and cost items are available on annual basis. However, in the case of unregistered manufacturing no current data exists, since production in this

sector is usually undertaken in the family based production units. As economic and non-economic activities in this sector are greatly intertwined an accurate measurement of the cost incurred in production becomes difficult. For estimating income in this sector, information available from various rounds of National Sample Survey is used.

For estimating net value added from the construction activity, expenditure approach is used. The method consist of estimating total expenditure on construction in the State and then bifurcating it into new construction and repair and maintenance. For this purpose total expenditure incurred on pucca construction, kuchha construction and land development etc. in the public sector and private sector, is estimated first. Of the total expenditure on pucca construction, 33.3 per cent is taken to constitute the gross value of the product generated under this sector. In case of kuchha construction and land development, this percentage is taken as 90. Net State Domestic Product from this industry is obtained, after making a 2 per cent allowance for depreciation from the gross value of the product.

In all other (remaining) sectors net domestic output is obtained by using the income approach. For organised segment of these sectors especially that relating to public sector like, Electricity Board, State Road Transport Corporation, State Warehousing Corporation and State Trading Corporation etc. income is estimated on the basis of current information on wages and salaries, interest, rents and operating surplus available from their annual accounts. In case of unorganised segment income is generally estimated as the product of the number of workers and per worker earnings obtained from various rounds of National Sample Surveys and studies undertaken by the DES at some points of time. Average per worker earnings for other years are obtained by moving the average value of earning in the survey year, with the help of some indicator (for details see Appendix A).

As mentioned earlier for activities of the supra-regional nature like railways, post and telegraphs, banking and insurance etc. which are not confined to the

boundaries of State only, State-wise allocation figures obtained from C.S.O. are used (for methodological details of sectoral income estimation see Appendix A).

4. Growth of Real Income : Its Behaviour and Trends

The object of this section is to measure economic growth in the State during the two decades from 1960-61 to 1980-81 with the help of real output series in the State.

4.1 Problems in Measurement and Choice of Time Period :

Real output, between any two points of time which are fairly apart, varies on account of two factors : (i) ability of the economy to produce goods and services or its productive potential; and (ii) changes in the ratio of actual production to potential production.¹⁷

Divergence between the rates of these two factors results in short-term fluctuations in actual output

¹⁷E.F. Denison, Sources of Economic Growth in the United States, op. cit., pp.3-4.

series around the potential level,¹⁸ and these short-term fluctuations are likely to overshadow the sustained increase in real output or economic growth¹⁹— unless the two end years chosen for the comparison of growth have some important basic similarities.

In under-developed agrarian economies, short-term fluctuations are caused by irregular farm output which itself depends on vagaries of monsoon and weather conditions. Measurement of economic growth in them, therefore, requires that the initial and the terminal years should not be much dissimilar in these respects. Our choice of the period 1960-61 to 1980-81 has been guided, firstly by the availability of data, secondly because the two end points do not show any marked dissimilarity in weather conditions; and thirdly because the chosen end points coincide with two Census years namely 1961 and 1981.

¹⁸Ibid, p.18.

¹⁹"By a sustained increase we mean a rise of such magnitude that is not overshadowed by short-term fluctuations If we have evidence of a sizeable movement, relative to the fluctuations over this long period, we can presume that the forces making for economic growth are marked and persistent", Simon Kuznets, Modern Economic Growth, IBH Publishing Company, Oxford, Indian Edition, 1972, pp.26-27.

4.2 Growth of Aggregate Real Income in U.P. : With our main objective stated and the time period specified we now present the estimates of real state domestic product and the series of index number prepared with the help of these estimates (Table II.1).

Table II.1 : Estimates of Net Real State Domestic Product and Its Indices in Uttar Pradesh at 1970-71 Prices

Years	Real SDP*(in crore Rs.)	Index of Real SDP
1960-61	3209.85	100.00
1961-62	3251.40	101.29
1962-63	3201.62	99.74
1963-64	3116.61	97.10
1964-65	3609.94	112.46
1965-66	3480.40	108.43
1966-67	3118.15	97.14
1967-68	3523.22	109.76
1968-69	3502.05	109.10
1969-70	3860.76	120.28
1970-71	4126.91	128.57
1971-72	3884.99	121.03
1972-73	4120.10	128.36
1973-74	3923.14	122.22
1974-75	4098.96	127.70
1975-76	4471.31	139.30
1976-77	4603.16	143.41
1977-78	5008.97	156.05
1978-79	5188.67	161.65
1979-80	4419.52	137.69
1980-81	5483.13	170.82

Source : State Income Estimates of U.P. Bulletin, Nos. 175 & 199, Economics & Statistics Division, State Planning Institute, U.P., Lucknow.

* For the reasons that would be explained latter the income generated under the sub-sector 'real estate and ownership of dwellings and business services' has been excluded.

According to Table II.1, real output in the State during the two decades has grown by 70.82 per cent. A closer examination however reveals that the growth experience of the two decades differ considerably. As an instance, real output during the first ten years i.e. 1960-61 to 1970-71 has grown by 28.57 per cent and in the second decade i.e. 1970-71 to 1980-81 by 32.86 per cent.

Table II.1 further shows that the real output has been fluctuating during the entire period, reflecting the underdeveloped nature of the State economy. But, the frequency of these fluctuations is considerably reduced during the second decade.²⁰ Decline in the frequency of income fluctuation during the second decade shows that the period 1970-71 to 1980-81 witnessed a higher rate of growth and stability as compared to the earlier period of the study 1960-61 to 1970-71. Differences in the growth performance of these two periods

²⁰ While during 1960-61 to 1970-71, real income in the State economy has fallen five times below its previous level, there are only three such declines during the latter decade 1970-71 to 1980-81.

are clearly revealed in Table II.2 which presents average compound growth rates of the State economy.

Table II.2 : Growth Rate of Real Output
in the State

Period	Growth rate ²¹ (in per cent per annum)
1960-61 to 1980-81	2.71
1960-61 to 1970-71	2.54
1970-71 to 1980-81	2.88

Source : Table II.1.

Growth rates given in Table II.2 show, that the real output during the two decades has grown by 2.71 per cent per annum. Growth rate during 1970-71 to 1980-81 happens to be .34 percentage points higher²² than during 1960-61 to 1970-71.

²¹ Average compound growth rates have been calculated using the formula $P_t = P_0 (1 + \frac{r}{100})^t$ where r is the rate of growth, t the value of the time variable and P_0 and P_t are the values of real output in the base and the final years respectively.

²² Differences in rates of growth measured even in tenths of the percentage points are important from the point of view of their end results. For example, if the national product grows at a rate of 4 per cent than at 3 per cent per annum, at the end of the twenty years it would be 21 per cent larger, and the increase in national product would be 44 per cent. See, E.F. Denison, Sources of Economic Growth in the United States, op. cit., pp.5-6.

4.3 Sectoral Growth : To understand the behaviour of aggregate real output in the economy and the trends revealed by it, a study of sectoral income growth and changes in the structure of real income will be useful. Sectors broadly considered for this purpose are the primary, secondary and tertiary. Indices of real output in different sectors have been presented in Table II.3. Table II.4 and II.5 present the implicit growth rates and percentage distribution of real product by broad sectors of origin.

A significant growth of real income has occurred in all the sectors (Table II.3). If we rank sectors according to their income growth, the secondary sector stands first with a growth of 207.74 per cent during the two decades under study. Second and third positions go to the tertiary and primary sectors respectively.

Primary Sector : Over the twenty years reference period selected for the study, real output in the primary sector has grown at an average compound rate of 1.77 per cent per annum (Table II.4). Rate of growth during

Table II.3 : Indices of Real Output in Broad Sectors

Years	S E C T O R S			
	Primary	Secondary	Tertiary	Total
1960-61	100.00	100.00	100.00	100.00

1960-61 to 1970-71	63.25	14.36	22.39	100.00
1970-71 to 1980-81	58.26	17.62	24.12	100.00

Source : Same as Table II.1.

the second decade 1970-71 to 1980-81 is .32 percentage points higher compared to the growth rate during the earlier decade 1960-61 to 1970-71.

It is apparent from Table II.3, that real output in this sector has fluctuated throughout. But, the frequency of these fluctuations is reduced during the second decade, for, there are only three years during this period when output has declined relative to its previous level whereas during 1960-61 to 1970-71 this phenomenon extended to six years. This shows that with the increasing use of high yielding variety of seeds, chemical fertilizers, better irrigation facilities and improved farm practices such as crop-mixing, crop rotation and cropping intensity during the second decade (1970-71 to 1980-81), real output in agriculture, the major sub-sector of the primary sector, has counteracted of to quite an extent the adverse effects/natural climatic conditions like weather and monsoon. Relative stability obtained during the latter decade may therefore be viewed as a significant change during thirty years of planned development.

A marked similarity in the behaviour of output is observed between the primary sector and the economy as a whole (Table II.3, col.1 & 4). Except the year 1961-62, change in total real output in the State economy has closely followed changes in the output of the primary sector. The reason, as Table II.5 shows, the sector contributed the largest share of the total real product — more than 60 per cent over the twenty years period (1960-61 to 1980-81). Due to its largest share, a small change in the output of this sector is likely to produce a greater effect in the total output of the economy in comparison to the other two sectors namely secondary and tertiary whose contributions to the total real product have been relatively small. And, it is for the low growth rates²³ observed in the primary sector during 1960-61 to 1980-81 (1.77 per cent per annum) that the over all growth of the economy remained

²³The average growth rate of total real product in the economy may be looked upon as the weighted sum of the sectoral growth rates, weights being the shares of the three sectors in the aggregate real product. See, B.H. Dholakia, Sources of Economic Growth in India, op. cit., p.21.

as low as 2.71 per cent per annum, though relatively higher growth rates were observed in the other two sectors.

Secondary and Tertiary Sectors : During the twenty years reference period (1960-61 to 1980-81) secondary and the tertiary sectors have grown at annual compound rates of 5.78 and 3.30 per cent respectively.

Analysis of the growth pattern of these two sectors shows that there have been fluctuations in the output of these two sectors also. But, the magnitude and frequency of fluctuations has not been as large as in the case of the primary sector. In case of the secondary sector, output has gone down four times (twice during each decade), while in case of the tertiary sector it has gone down once in the first decade, and twice in the second decade. Thus, growth in these two sectors has been relatively steady compared to the growth in the primary sector. While both sectors have grown during the reference period, a matter of great concern is that there has been a decline in the growth rate of the secondary during the second decade 1970-71

to 1980-81 as compared to 1960-61 to 1970-71 while the tertiary sector has improved its growth rate by .20 percentage points during the same period.

4.4 Structure of Real Income : The structure of real income reveals a decline of 4.99 percentage points in the share of the primary sector during 1970-71 to 1980-81 in comparison to its percentage share during 1960-61 to 1970-71 (Table II.5). Percentage shares of both secondary and tertiary sectors mark an increase 1.26 and 1.73 percentage points during the second decade as compared to their respective shares during the first decade.

A shift in the structure of real income, with a gradual decline in the percentage share of the primary sector and increase in the shares of secondary and tertiary sectors is a common feature of economic development. It is noteworthy however, that the share of the commodity producing sector²⁴ has declined during the

²⁴ Share of the commodity producing sector is obtained by adding the shares of primary and the secondary sector.

latter decade (1960-61 to 1970-71). While this seems to have occurred due to the slow-down in the growth rate of the secondary sector during 1970-71 to 1980-81, expansion of the service sector with a decline in the share of the commodity producing sector can not be regarded as conducive to the balanced development and is likely to have flared up the rate of inflation in the economy.

4.5 Further Analysis of Growth of Real Output : The decadal growth performance, however fails to bring out the process of growth of the State economy. It can be seen from Table II.1 that the index of real output reveals a zig-zag movement and registers a dismal growth up to 1966-67. However, it shows a sustained increase since 1974-75 except for a fall during 1979-80 which was a bad agricultural year. As the new agricultural technology or the High Yield Variety programme was introduced in the State in the mid-sixties, it can be generally presumed that a positive change started

occurring in the economy by 1967-68.²⁵ Hence a study of the growth performance of the State economy with two break-in points at 1967-68 and 1974-75 seems appropriate. Growth rates calculated for the three sub-periods 1960-61 to 1967-68, 1967-68 to 1974-75 and 1974-75 to 1980-81 for the aggregate and sectoral incomes have been presented in Table II.6.

Table II.6 : Average Growth Rates of Real Income in U.P.

Period	(in per cent per annum)			
	All sectors	Primary	Secondary	Tertiary
1960-61 to 1967-68	1.34	.41	4.48	2.41
1967-68 to 1974-75	2.19	1.33	4.25	3.16
1974-75 to 1980-81	4.97	3.90	9.16	4.52

Source : Table II.3.

²⁵ While the year 1966-67 marks the end of the pre-HYV period, being a severe drought year in the State, it does not provide a satisfactory basis for computing compound growth rates which are sensitive to the choice of the end-points. Moreover, the new agricultural technology which was introduced in June 1965 is likely to have taken some time to show up some significant results. The choice of 1967-68, as a break-in point seems reasonable in this respect.

As the apriori reasoning suggests, growth rates during 1967-68 to 1974-75 are .25 percentage points higher compared to the growth rates during 1960-61 to 1967-68 and growth rates during 1974-75 to 1980-81 are 2.78 per cent²⁶ higher compared to the rates during 1967-68 to 1974-75. It appears therefore, that the State economy which experienced a negligible growth up to 1966-67 started looking up from 1967-68 onwards. However, a real stride seems to have come since 1974-75 which is manifested in the high growth rates during 1974-75 to 1980-81 and also thereafter.²⁶

Except the secondary sector where growth rates during 1967-68 to 1974-75 declined in comparison to the rate during 1960-61 to 1967-68, other two sectors of the economy namely primary and the tertiary reveal considerable improvement in their growth since 1967-68.

²⁶Viewing the performance of the State economy during the Fifth and Sixth Plan periods, it is now generally believed that the State economy has picked up the momentum of growth since 1974-75. See, (i) A.K. Singh, Uttar Pradesh Economy : Poised for Rapid Growth, The Economic Times, December 19, 1986, and (ii) T.S. Papola, and Fahimuddin, "Industrial Spurt in Uttar Pradesh : Myth or Reality?" The Economic and Political Weekly, February 16, 1985, pp.269-273.

Growth rates in the primary sector during 1967-68 to 1974-75 are 0.92 percentage points higher compared to the growth rates during the pre-HYV period i.e., 1960-61 to 1967-68. With the spread of green revolution and farmers response to new agricultural technology, growth rate in this sector showed further improvement during 1974-75 to 1980-81, being 2.57 per cent higher than during 1967-68 to 1974-75.

In case of tertiary sector also growth rate during 1967-68 to 1974-75 reveal an improvement of 0.72 percentage points over that during 1960-61 to 1967-68. Growth rate during 1974-75 to 1980-81 is 1.36 per centage points higher as compared to that during 1967-68 to 1974-75; Improvement during 1974-75 to 1980-81 being 2.57 per centage ,points than during 1967-68 to 1974-75.

It is indeed encouraging to find out spurt of growth in the secondary sector during 1974-75 to 1980-81. The sector has improved its growth rate by 4.91 percentage points during 1974-75 to 1980-81, over that experienced during 1967-68 to 1974-75.

4.6 Conclusions

Main conclusions emerging from the above analysis are :

1. During the twenty years period as a whole, real product in the State has grown at an average compound rate of 2.71 per cent per annum.
2. The rate of growth was phenomenally slow upto 1967-68. But, from 1967-68 onwards, the graph of growth started rising up, and after 1974-75, it shows an encouraging and steady upward trend.
3. Throughout the two decades 1960-61 to 1980-81, real output in the State has been dominated by the behaviour of output in the primary sector.
4. Decade-wise, 1970-71 to 1980-81 has experienced more growth and stability compared to the decade 1960-61 to 1970-71.
5. Relative stability and speedier growth during the latter decade (1970-71 to 1980-81) has been due to the growth and stability achieved in the primary sector and improved performance of the secondary and tertiary sectors, particularly during 1974-75 to 1980-81.

6. The State economy has experienced a shift in sectoral output in favour of the tertiary sector during the second decade. To some extent, relative gain of the tertiary sector, has been due to the decline in the growth rate of the secondary sector. This phenomenon, does not indicate a healthy trend for the State economy and calls for strengthening the industrial sector.
7. Despite a gradual decline in the percentage share of the primary sector in total real product during the twenty years under study, more than half of the total output still originates in this sector. Thus, given its structure, not much improvement in the overall growth rates of the economy can be expected, unless the rate of growth of the primary sector improves appreciably.

Appendix A

For the purpose of computation of State income all the economic activities in the State have been classified under 13 major heads as mentioned in the text earlier. The method of income estimation and data base in each of these sectors is given below.

Agriculture (including Animal Husbandry)

Net value of output in this sector is obtained by subtracting from the gross value of output, cost of all the inputs including depreciation incurred in the production. Gross value from this sector is obtained separately for crop production and animal husbandry. However, as agriculture and livestock activities are usually carried out together, the two subsectors are treated as one for the purpose of estimating total cost of input.

Gross output in agriculture is first worked out in physical terms by using area and out-turn figures supplied by the Directorate of Agriculture/Board of Revenue U.P. Gross value is then worked out by

multiplying the gross output figures by the corresponding weighted average prices relating to the post-harvest peak marketing period. Adjustments are also made for the rice milling charges and higher and lower value of procured food grains.

For most of the crops, area figures are available but out-turn figures are not. These crops for which out-turn figures are not available, are evaluated on the basis of information on average yield of some other specified crops for which out-turn figures are available. This of course introduces an element of guess-work in estimation. However, area and production figures for major crops being available, gross output estimates for this sector are fairly reliable.

Gross output from animal husbandry, is estimated on the basis of quinquennial livestock censuses in the State. Gross output for different products, is estimated by multiplying number of animals in each category, by the average yield per animal provided by State Directorate of Animal Husbandry/Directorate of Marketing and Inspection or Central Statistical

Organisation.¹ Gross output is then evaluated using prices of these products, after making due allowance for trade and transport margin and rural-urban price variations. Estimates of number of animals of the relevant categories for the inter-censal years, are obtained by interpolating the bench mark estimates, assuming a constant geometric rate of growth.

To arrive at the net value added from crop production and animal husbandry sector, certain deductions for cost of inputs like seeds, manures, cost of live-stock feed, insecticide, pesticide, diesel oil, irrigation charges, current repair and maintenance etc. are made from the gross value of the output (crop production and animal husbandry). In the absence of any record of expenditure on cultivation no firm and current data on cost items are available at the State level. Cost estimates provided by C.S.O. are used. However, attempt is made to use the revised rates to various items of inputs on the basis of latest available information.

¹Hereafter referred as C.S.O. only.

Forestry

Production method is used for this sector also. For official exploitation of major forest products, out-turn and prices are available from the State Forest Departments. These prices are duly adjusted for trade and transport margins before using them for evaluation. Value of gross output so arrived is inflated by 10 per cent to account for unauthorised exploitation. As no out-turn figures in case of minor products (except bamboo) are available, their value is estimated in terms of royalty.

In the absence of data on cost of inputs and depreciation for this sector in the State, a certain percentage, as suggested by C.S.O. is deducted, to arrive at the net value added.

Fisheries

Income from this sector is estimated, on the basis of data supplied by State Fisheries Department. The department provides data on total production of fish as well as prices. Weighted average wholesale prices of different varieties of fishes are used.

Since no data on cost of fishing in the State are available deduction rates suggested by C.S.O. are used.

Mining and Quarrying

As mining in the State is mostly in the nature of an organised activity, current and reliable data are available both for prices and output. In case of major minerals, these figures are obtained from the Director of Geology and Mining. For mining in the unorganised sector, information available from reports of National Sample Survey is utilised. To arrive at net value added in this sector, deductions for cost and depreciation are made on the basis of rates suggested by the Indian Bureau of Mines, Nagpur.

Manufacturing

For the purpose of income estimation manufacturing sector has been divided under two subsectors (i) registered manufacturing, and (ii) unregistered manufacturing.

Registered Manufacturing : For estimating output from this sector fairly reliable and current data on output, input, depreciation etc. are available from the Annual

Survey of Industries.² Using these data net value is obtained as total output - (total input + depreciation). The figure arrived is adjusted for imputed banking charges provided by the C.S.O.

Unregistered Manufacturing : Due to extreme dearth of relevant data State level income estimation for this sector was not undertaken upto 1977-78. Percentage share of this State (10.86) in the unregistered manufacturing sector for all-India in 1960-61, was adopted for other year also. However since 1978-79, estimates are prepared at the State level. For this purpose all the manufacturing units in this sector have been grouped under 10 major industry groups. Estimates of gross value added for the non-household sector in 1974-75, are obtained directly from the C.S.O. and are based on the data available from the centrally sponsored scheme on Survey of Small Scale Industries (CSSI) and all-India Report on the Census of Small Scale Industrial Units published by the Development

²The ASI data on complete enumeration basis are available from 1967 onwards only. Hence for years prior to 1967 net value added were obtained by adding estimates of Census sector and sample sector for this State from NSS reports". See, Methodology of State Income Estimates of Uttar Pradesh (revised series), State Planning Institute, Economic & Statistics Division, Lucknow (January 1977), p.25.

Commissioner Small Scale Industrial Units. Estimates of gross value added for the household sector are based on the NSS-29th Round.³ Estimates for household and non-household sector for 1974-75 are added. These are adjusted for the consumption of fixed capital at the rates suggested by C.S.O. and are moved to other years with the help of physical indicators of output/input. Constant price estimates so derived are converted at current prices with the help of price indices of relevant commodity groups and are corrected with the help of an adjustment factor.⁴

Construction

This sector includes all the construction, repair and maintenance and demolition work in the State carried out by Government (Central and State), departmental and non-departmental commercial undertakings and the private sector.

³Report No.280/3, Tables with Notes on Survey of Self-employed Households in Non-agricultural Enterprises: Detailed Results, 29th Round (July 1974-June 1975), National Sample Survey Organisation, Ministry of Planning, Govt. of India, 1978.

⁴The adjustment factor has been prepared with the help of State estimated figure and CSO estimated figure for this sector in U.P. in the year 1977-78. See, State Income Estimates, Bulletin No.199, Economic & Statistics Division, State Planning Institute, U.P., p.34.

For evaluation of value added by the construction activity expenditure approach is used. The method consists in estimating the total expenditure on construction and on (ii) expenditure on repairs and maintenance. A certain proportion of total expenditure is taken as value added by the construction activity. This proportion is different for kuchha and pucca construction as well as for new construction and repair and maintenance. To arrive at net value added deduction is made for depreciation.

Data base for estimating value added from this sector is not very firm. Although figures of expenditure on construction undertaken by Central Govt., State Govt. and local bodies are available, there are problems in estimating expenditure on construction by some departmental and non-departmental undertakings whose activities extend to many States such as Post and Telegraph, Railways, Life Insurance Corporation etc. Expenditure incurred by these establishments is either obtained from C.S.O. or is culled from their annual accounts.

No current data on household expenditure on construction either in the rural or in the urban sector are available.

For rural household sector bench mark estimates of expenditure per person on pucca and kuchha construction obtained from the studies⁵ carried out by State Statistical Bureau⁶ at different points of time. These are interpolated and extrapolated to obtain estimates for other years and are multiplied by mid year annual population. The figures obtained are deflated by the index of wages, of rural unskilled labour to arrive at figures of total expenditure on construction by the rural household sector.

For urban household construction also, current data do not exist. Same method of moving forward and backward estimates of per household expenditure on pucca and kuchha construction available from NSS Reports⁷ and studies undertaken by SSB is adopted. The figures are multiplied by number of urban households and deflated

⁵ (i) Capital Formation by Households in Rural Areas of Uttar Pradesh (1959-60); and

(ii) Capital Formation in Rural Areas of Uttar Pradesh, (1969-70), State Statistical Bureau, U.P.

⁶ Hereafter referred as SSB only.

⁷ Capital Formation in Urban Areas of Uttar Pradesh, Report No.136, National Sample Survey Organisation, Cabinet Secretariate, Govt. of India, New Delhi.

with the wage indices of rural skilled labour to arrive at total expenditure on construction in different years.

Electricity, Gas and Water Supply

Value added in this sector is obtained by using income approach. In case of electricity estimates of factor incomes are obtained from the annual accounts of UPSEB.⁸ For private companies and municipal corporations in this sector, state level data is not available. Value added for them, is therefore obtained on the basis of sale of energy by these units, in the State.

Income from water supply, is obtained on the basis of wage and employment data, available from the municipalities. Compensation to employees is estimated on the basis of this data. For other factor incomes, figures are culled from annual survey of industries.

In case of gas, value added in this State is taken as negligible.

Transport, Storage and Communication

From the point of view of income estimation, economic activities in this sector have been classified under

⁸Uttar Pradesh State Electricity Board.

three heads viz. (i) Transport, (ii) Storage, and (iii) Communication. Separate estimation for each activity is undertaken by using income method.

Transport includes railway transport, road transport (mechanised and non-mechanised), air and water transport and services incidental to transport like *packing, crating, travel agency services etc.

For railway transport no estimation is undertaken at the State level. State-wise allocation⁹ figures supplied by C.S.O. are used.

SDP from mechanised and non-mechanised road transport is estimated separately. In case of public sector current data are obtained from State Road Transport Corporation, U.P. No current data on mechanised road transport in the private sector are available. Income is estimated by using the information available from NSS report.¹⁰ Value added per worker for rural and urban

⁹For method of allocation of SDP from rail transport to different States kindly refer National Account Statistics : Sources and Methods, C.S.O., Ministry of Planning, Govt. of India, 1980.

¹⁰ NSSO-29th Round, op. cit.

sectors obtained from the report for 1974-75 are moved to other years with the help of the index of wages of rural skilled labour and consumer price index of urban skilled labour. These figures are multiplied by the working force engaged in mechanised road transport (bench mark estimates are moved to other years with the help of number of vehicles on road).

In case of non-mechanised road transport studies under-taken by Economic and Statistics Division, SPI are relied upon.

For water transport and services incidental to transport, the only information available is the number of workers. Average earnings per worker in this sector are taken to be the same as in the non-mechanised road transport.

In case of air transport also data coverage is incomplete. Information provided by Hind Flying Club and Indian Air Lines is used.

Communication

In case of communication also no estimation at State level is undertaken. Value added figures as supplied by C.S.O. are adopted.

sectors obtained from the report for 1974-75 are moved to other years with the help of the index of wages of rural skilled labour and consumer price index of urban skilled labour. These figures are multiplied by the working force engaged in mechanised road transport (bench mark estimates are moved to other years with the help of number of vehicles on road).

In case of non-mechanised road transport studies under-taken by Economic and Statistics Division, SPI are relied upon.

For water transport and services incidental to transport, the only information available is the number of workers. Average earnings per worker in this sector are taken to be the same as in the non-mechanised road transport.

In case of air transport also data coverage is incomplete. Information provided by Hind Flying Club and Indian Air Lines is used.

Communication

In case of communication also no estimation at State level is undertaken. Value added figures as supplied by C.S.O. are adopted.

Storage

For warehousing and cold storage net-domestic product is obtained using current data on factor incomes available from State warehousing corporation U.P. and Annual Survey of Industries.

Trade, Hotels and Restaurants

All the wholesale and retail trading activities including export, import and auctioneering come within the purview of this sector.

Income method has been used for those wholesale and retail traders who are assessed for the purpose of income tax. Data on number of trading units and their incomes are obtained from the income tax department.

For all the trading units not registered for the purpose of income tax gross income per worker is obtained on the basis of NSS report. Per worker values are multiplied by number of workers engaged in these trading activities. Depreciation at the national level is deducted to arrive at the net value added.

Banking and Insurance

For most of the banking and insurance services State-wise allocation figures supplied by CSO are used. For the financial institutions whose activities are of localised nature factor incomes are estimated by the analysis of their annual accounts.

Real Estate and Ownership of Dwellings

This sector includes activities of real estate dealers and the income originating from the ownership of residential dwellings.

In case of ownership of dwellings per person rental in the urban sector for 1967-68 given in SSB report¹¹ is moved to other years with the help of year-wise ... rental value per residential house for the municipal houses. There being no reliable data for the rural sector, rental per person in rural area is taken as 1/3 of the urban areas. The estimates are multiplied by the number of Census houses in urban and rural sectors separately and added to get the gross rental from ownership of dwellings. Number of houses during inter-censal

¹¹Uttar Pradesh Me Awason Ki Dasha 1967-68, Bulletin No. 138, SSB.

years are obtained by interpolation and extrapolation assuming geometric rate of growth. Current and reliable data on cost of maintenance and repair is also not available. Hence, percentages as at the national level are used.

For real estate SDP in 1960-61 for this sector was obtained from CSO. This allocation to the State was based on the basis of working force. For other years net product per worker in real estate is moved forward with the help of index of annual average earnings of factory worker. These figures were multiplied by the projected number of persons in real estate. The product gave estimates of SDP for real estate at current prices.

Estimates of ownership of dwellings and of real estate, are added together to give the SDP from this sector.

Public Administration

SDP from this sector is the total of wage and salaries, honoraria (excluding travelling allowance) pension, employers contribution to provident fund and all wage supplements in cash or kind.

For the administrative services of the Central Government data is obtained from CSO. For State Government, estimates of expenditure on wages and salaries is obtained from their budget accounts. As expenditure on administrative staff alone is required, expenditure on wages and salaries of the government staff engaged in other commercial undertakings such as railway, education and health etc. is subtracted from it.

Estimation of SDP for Local Bodies is based on the analysis of their annual accounts.

Other Services

This sector includes education, research, medicine, sanitary, religious and community services, legal services, recreation and entertainment services, personal service and services not specified elsewhere.

To facilitate income estimation all the activities in this sector have been regrouped under four groups viz. (i) education and research, (ii) medical and health, (iii) sanitary services, and (iv) all other services. The method has been to estimate SDP for each group, as a product of per head earning in the group and the working force. SDP for each group is added to get the final estimate of SDP from this sector.

Chapter III

FACTOR INCOMES BY DISTRIBUTIVE SHARES IN U.P.

Our aim in this chapter is to develop a set of weights for combining the indices of the three factor inputs land, labour and capital growing probably at different rates over the period of study. Two approaches are generally adopted for developing such weights. One is to use relative factor price ratios of the three factors in the base year¹ and develop relative weights on the basis of relative price ratios. Another variant is to derive the set of weights on the basis of relative income shares of the three factors in the value added.² It is the latter approach that would be used for the purpose of this study.

Data for preparation of factor shares are not readily available in the State. Lack of the requisite data and absence of sustained efforts to obtain the functional break down of State income have resulted in a complete

¹J.W. Kendrick, Productivity Trends in the United States, Princeton University Press for NBER, 1961.

²E.F. Denison, Sources of Economic Growth in the United States and the Alternatives Before Us, Supplement Paper No.13, Committee for Economic Development, New York, January 1962.

dearth of factor income estimates for the State. Though data are not easy to get for the national economy as well, yet many attempts have been made to provide factor income estimates at the level of the country as a whole.³ The Central Statistical Organisation (C.S.O.) has also started providing functional break-down of National income since 1960-61.⁴ Yet, to our knowledge, no attempt, either officially or unofficially, has so far been made to provide corresponding estimates at the State level. Hence a

modest attempt has been made here to obtain the functional distribution of State income in U.P. during 1960-61 to 1980-81. The chapter has been presented into two parts : Section I is devoted to the preparation of factor shares in different sectors and Section II analyses the trends in the relative movement of factor shares over-time.

Section 1 : Estimation of Factor Incomes

1.1 Preliminary

Theoretically, factor income estimates refer to four types of income flows relating to four traditionally accepted factors of production: labour, land, capital and enterprise. The corresponding income flows are termed as wages and salaries or compensation to employees, rent, interest and profit. It is not, however, always possible to identify and measure all the four income flows separately. Difficulties arise due to the presence of large unorganised sector where major portion of value added is the combined share of all the factors of production called "mixed income of the self-employed". A functional break-up of net value added is not therefore possible without resorting to a set of assumptions. As a consequence, estimates developed here remain tentative only.

Nevertheless they reveal the broad trends in the movement of factor shares over-time and yield a set of weights that serves our purpose.

Since our study deals with three broad sectors of the economy viz. primary, secondary and tertiary, factor shares have been prepared on the sectoral basis. Except in the case of primary sector where estimates of all the four factors have been derived, in the remaining two sectors shares in respect of only labour and capital (including land) have been prepared. In some cases, where State level data for preparation of factor shares could not be available, All-India ratios as given in NAS have been used.

1.2 Factor Shares in the Primary Sector

The primary sector comprises of agriculture (including animal husbandry), forestry and fisheries. Shares for all the sub-sectors have been derived separately and added together to obtain the estimates of factor shares in this sector. Procedure of estimation of factor shares in the agricultural sector is given below.

1.2.1 Factor Shares in Agriculture : While there has been some general awareness among economists about the growing inequalities in agricultural income, especially after the introduction of HYV programme, no comprehensive attempt to provide the estimates of factor incomes and changes in these shares over-time has been made so far at least for the State. Recently however, a few studies have been undertaken at the regional and lower levels of disaggregation. Studies by Haque and others,⁵ J.P. Singh,⁶ M.V. George and others⁷ are aimed at highlighting the differences in the trends in factor income shares among regions of the country. These authors no doubt, provide percentage share of factors in agricultural income during mid and late seventies but they are based on the analysis of only one or two crops. Then, there have been some

⁵T. Haque, V.K. Sharma and M.S. Bhatia, "Temporal and Spatial Variations in Factor Shares in Indian Agriculture", Indian Journal of Agricultural Economics, Vol. XXXVIII, No.3, July-Sept. 1983, pp.391-399.

⁶J.P. Singh, "Factor Shares in Indian Agriculture", Indian Journal of Agricultural Economics, Vol. XXXVIII, No.3, July-Sept. 1983, pp.429-434.

⁷M.V. George, N.J. Kurian and C. Chandra Mohan, "Factor Shares in Indian Agriculture, Temporal and Spatial Variations and Their Implications", Indian Journal of Agricultural Economics, Vol. XXXVIII, No.3, July-Sept. 1983, pp.399-406.

studies confined to a village or a block.⁸

In view of a large number of crops grown each year and wide variations in the agro-climatic conditions among regions in the State, the results of these studies are rather inadequate for our purpose. Hence, an independent exercise has been undertaken to prepare shares for crop production and animal husbandry on the basis of available data. Shares of the primary factors, labour, capital and land corresponding to the income flows viz., wages and salaries, interest, and rents have been estimated independently for crop production and animal husbandry. Deducting the sum total of the estimated shares of land, labour and capital, from the estimates of net value added in the agriculture sector, as made by Economic and Statistics Division, State Planning Institute, profit, the share of the fourth factor 'enterprise' has been obtained. A brief account of the data base, concept used, and the method of preparing these estimates is given below.

⁸Ram Iqbal, V. Prasad and S.M. Dingar, "Changes in Relative Factor Shares in Agricultural Production (A Case Study)", Indian Journal of Agricultural Economics, Vol.XXXVIII, No.3, July-Sept. 1983, pp.445-446.

1.2.1(a) Factor Shares in Crop Production* : For the purpose of preparing factor incomes the whole period of twenty years has been broken into two sub-periods, 1960-61 to 1969-70 and 1970-71 to 1980-81.

No systematic data on cost of cultivation required for preparing factor income estimates are available for either of the two periods, except from the farm management surveys carried out in the State at different points of time. It is only recently that Directorate of Agricultural Research Statistics has started collecting data on various aspects of cost of cultivation under the scheme entitled "comprehensive scheme for studying cost of cultivation/production of principal crops". (here-after referred as the comprehensive scheme). While for the period 1970-71 to 1980-81 data collected under the above mentioned scheme have been utilized, for period 1960-61 to 1969-70 we have relied on data available from "Studies in the Economics of Farm Management in U.P." in Deoria and Muzaffarnagar districts of Uttar

* A brief account of the data base for preparing factor income estimates in the animal husbandry sub-sector would be given when we come to the preparation of factor shares in that sub-sector.

Pradesh.⁹ These two studies¹⁰ provide data on various aspects of cost of cultivation for three consecutive years from 1966-67 to 1968-69. Also, Deoria and Muzaffarnagar districts are considered to be adequately representative of eastern and western regions of the State, and therefore estimates relating to them provide a good basis for generalisation of results for the State of Uttar Pradesh (for details see Appendix B).

It may also be mentioned that concepts, definitions and the basis of evaluation of various farm inputs used in the farm management studies and "Comprehensive Scheme for Studying Cost of Production and Out-turn of Principal Crops" are similar, so that, the results drawn from the two sources are quite comparable.

The main assumption underlying the preparation of factor income estimates is that the share of factor in

⁹ (i) Studies in the Economics of Farm Management in Deoria, Uttar Pradesh, Combined Report 1966-69, Directorate of Economics & Statistics, Ministry of Agriculture, Govt. of India, Undated.

(ii) Studies in the Economics of Farm Management in Muzaffarnagar District, Uttar Pradesh, Combined Report 1966-69, Directorate of Economics & Statistics, Govt. of India, 1975.

¹⁰ Hereafter referred as EMS only.

the value added are equal to the share of factors in the total cost. Total cost of cultivation (per hectare) as given in FMS and the comprehensive scheme has therefore been regrouped under the following heads.

1. Wages : Wages or labour costs represent the payment made by the farmer to the labour engaged in various farm activities such as sowing, tilling, harvesting etc. As bulk of the labour engaged in farms comes from the farm families themselves, it has also been evaluated¹¹ at the rate paid to the permanent labour. Total wages worked out thus represent the share of labour in value added.

2. Interest : Interest paid in cash or kind for the capital goods including an imputed value for those items of capital which are supplied by the farmer himself, measure the share of capital. Interest charges to different crops have been allocated in proportion to area under the crop to gross area sown.

¹¹The basis of evaluation of family labour hired labour and all other factor inputs like rent and rental value of owned land etc. and also the method of allocation of total cost to different crops mentioned here are those used by FMS and the comprehensive scheme. Both the sources however use same basis for evaluation of inputs and allocation of cost.

3. Rent : Payments made in cash or kind in the form of land revenue, taxes, lease rents, etc. are included under this head. Since most of the land under self-cultivation is acquired by farmers by way of inheritance, an imputed value at 5 per cent of the value of land at village price has been assigned for the owned land. This value has been allocated to different crops in proportion to the area under the crop to gross area sown on owned land.

It may also be noted here that the two farm management studies (Muzaffarnagar and Deoria) and the comprehensive scheme provide information about crops covering more than 60 per cent of the total sown area in the State during the reference period 1960-61 to 1980-81.¹² For no better alternative, factor shares for remaining 40 per cent of the area have been assumed to be the same as for the crops covered under FMS in case of Period I and under the comprehensive scheme in case of Period II.

In preparing factor shares for crop production, the practice has been to multiply per hectare estimates

¹² Calculated on the basis of information about area under different crops and total area sown in the State, published in various issues of Agricultural Statistics of Uttar Pradesh, Department of Agriculture, Govt. of U.P.

of different factors for various crops by the area under these crops. For the crops for which per hectare estimates were not available, average per hectare estimates of the crops covered by FMS and comprehensive scheme have been used for Period I and II respectively. As FMS (1966-69) could be used to prepare factor income estimates for the years 1966-67, 1967-68 and 1968-69 only, in order to obtain factor income estimates prior to 1966-67 information available from Farm Management study (1954-57) in U.P.¹³ has been utilized. Shares of labour and capital for the years 1960-61 to 1965-66 have been obtained by observing the changes in shares between 1954-57 and 1966-67 and distributing the total change uniformly over the years. As FMS (1954-57) did not include rental value of owned land in the total cost of the included crops, per hectare value of land in 1966-67 has been moved backward, with the help of index of total area sown and index of wholesale prices of agricultural

¹³ Studies in Economics of Farm Management in Uttar Pradesh, Combined Report (1954-55 to 1956-57), Directorate of Economics and Statistics, Ministry of Agriculture, Govt. of India.

commodities in the State. Similarly in Period II also, gaps in factor income estimates for the years for which comprehensive scheme data could not be available, have been filled up, by using the observed trends in the movement of per hectare shares between the years for which data are available.

As agricultural sector in the State includes activities of State irrigation works also, estimates of wages and salaries and interest in the case of public irrigation have been obtained from annual administration reports of the Irrigation Department, U.P.¹⁴ In case of irrigation works, share of land has been assumed to be negligible.

Absolute shares of wages, interest and rents in case of crop production including irrigation have been presented in Table III.1

¹⁴ Uttar Pradesh Sinchai Vibhag Ka Karyapurti Digdarshak, Department of Irrigation, Govt. of Uttar Pradesh (different issues).

* Includes irrigation also.

1.2.1(b) Shares of Major Factors in the Animal Husbandry Sub-sector : As there are various problems in the allocation of costs between agriculture (crop production) and livestock activities which are usually carried together, the subject of preparation of factor shares for the animal husbandry sub-sector has remained relatively unexplored. In what follows an attempt has been made to provide estimates of major factor incomes (i.e. absolute shares of labour and capital) in this sub-sector. The assumption that shares of factors in the value added are equal to the shares of factors in the total cost, holds good for this sub-sector also, as in the case of crop production.

Output of the animal husbandry sector consists of a number of group of products such as : (i) milk and milk products, (ii) meat and meat products, (iii) eggs and poultry, (iv) hides and skin, (v) wool and hair, (vi) dung, (vii) bones, (viii) increment in livestock, and (ix) other products.¹⁵ However, nothing substantial is known about the value of labour and capital involved in the production

¹⁵ Methodology of State Income Estimates of Uttar Pradesh (revised series), Economic and Statistics Division, State Planning Institute, U.P., 1977, p.13.

of these products except milk. Even for milk, production data are neither current nor regular. Yet, as milk and milk products occupy the most prominent place in the gross value from this sector,¹⁶ stray information available about the milk economy has been used as the basis, for evaluating factor shares for the sector animal husbandry.

1.2.1 (b-1) Shares for Milk Production : As mentioned earlier data for milk production in the State are rather scarce, except from a few farm management studies, and a few cattle surveys, which provide some information about the cost of milk production. Fortunately the two studies of Deoria and Muzaffarnagar which have been used for estimating labour and capital component in case of agriculture contain some information on various aspects of maintenance cost of cows and she buffaloes also. This information has been used for estimating labour and capital components in case of milk production. As the

¹⁶ Working Sheets of the State Income Estimates, Economic & Statistics Division, State Planning Institute, Lucknow (Uttar Pradesh) show that milk and milk products account for the major share of the gross value of animal husbandry. Percentage share for 1960-61, 1970-71 and 1980-81 are 72.87, 66.48 and 72.58 respectively.

studies provide cost of maintenance of milched animal for agricultural households only (having some cultivable land), we have assumed that cost of maintaining milched animals for the non-agricultural households would be the same as for the agricultural households. While the assumption may not be perfectly true, the number of milched animals with the non-agricultural households being too small in comparison to the agricultural households, our results are not likely to err to a questionably large extent.¹⁷

Share of labour per cow and per she-buffaloe obtained from FMS has been multiplied by the number of milched cows and she-buffaloes in milk, to get the total share of labour in milk production for years 1966-67, 1967-68 and 1968-69. Estimated share for 1966-67 has been moved backward and that of 1968-69 forward, with the help of total number/^{of} milched cows and buffaloes and the index number of average wages of other agricultural labour in the State.

¹⁷ According to 1972 Livestock Census about 96.24 per cent of the total milched buffaloes and 97.06 per cent of the total milched cows were in the rural sector of the State and as most of the household in the rural sector are agricultural household, having some cultivated land, our assumption is not likely to take us too far from the reality. See, Livestock Census of U.P. 1972, Directorate of Economics & Statistics, Ministry of Agriculture, Govt. of India.

Share of capital in milk production for the years 1966-67, 1967-68 and 1968-69 has been estimated by multiplying the interest charges per cow and per she-buffaloe by the total number of milched cow and buffaloes in the State in the respective years. In order to obtain estimates for years 1960-61 to 1965-66 it has been assumed that percentage change in the share of capital in this sub-sector would be the same as in crop production during 1960-61 to 1966-67. Per cow and she-buffaloe capital component thus worked out for 1960-61, has been multiplied by the number of milched cow and buffaloe in the year, to derive total capital share in milk production in 1960-61. Per milched animal estimates for the intervening years have been obtained by distributing uniformly over the years, total percentage change in the capital share per milched animal between 1960-61 and 1966-67. Estimates so derived have been multiplied by the total number of milched cows and buffaloes in the respective years to get the share of capital for years between 1960-61 and 1966-67. Same procedure has been used to obtain the share of capital for the years 1969-70 to 1980-81.

As in NAS,¹⁸ share of land in the animal husbandry sector is assumed to be negligible. Absolute share of labour and capital so worked out are given in Table III.2 (for detailed methodology of preparing these shares see Appendix B₂).

1.2.1(b-2) Shares of Factors in Case of Non-milk Products:

Besides cow and buffalow milk there are certain other products like meat, eggs and poultry, hides and skins, wool and hair and bones etc. which are contributed by different categories of livestock. Since there are no detailed studies which could provide us information about the labour and capital used in rearing these other types of livestock and in the operational cost associated with the production of these products, the entire population of livestock relevant for this purpose has been converted into milch cow equivalents with the help of cattle equivalence ratio.¹⁹ These numbers have then been multiplied by labour and capital component per cow (as obtained from FMS for milk production) to obtain total labour and capital component in case of non-milk products (see Appendix B₃).

Total labour (wages and capital (interest) component in case of non-milk products have been shown in Table III.3.

¹⁹The cattle equivalence ratio refers to the scale of converting different categories of animals (including poultry) in terms of cattle on the basis of their average feed consumption. See, Methodology of State Income Estimates (revised series), op. cit., p.20.

Having now prepared estimates of the shares of labour, capital and land for the two sub-sectors agriculture (crop production) and animal husbandry, we add them together and subtract from the net value added figures available from Economic & Statistics Division, SPI, to obtain the estimates of profit, the share of the fourth factor - enterprise. Shares of the four factors land, labour, capital and enterprise have been shown in Table III.4.

* Includes State Irrigation Works also.

1.2.2 Factor Shares for Other Sub-sectors in the Primary Sector : The sectors forestry and fisheries are not very important sectors so far as their contribution to the net value added in the State is concerned.²⁰ Further, availability of data for these sectors to estimate factor shares at the State level is highly limited. No attempt has therefore been made to prepare independently factor income estimates for these sub-sectors. Instead, shares have been prepared from all-India percentage share of the factors on the basis of NAS data. NAS however, provides five categories of factor incomes : (i) compensation to employees, (ii) interest, (iii) rent, (iv) profits, and (v) mixed incomes of the self-employed persons.²¹

²⁰ During 1970-71 to 1980-81 percentage contribution of the forestry sector to total SDP in the State ranged between 1 to 1.5 per cent. and that of fisheries between 0.1 to 0.2 per cent. See, Table 7, Bulletin No. 199, State Income Estimates of U.P., 1970-71 to 1982-83, Economic and Statistics Division, State Planning Institute, U.P.

²¹ See, different issues of National Account Statistics, op. cit.

In the absence of any scientific basis, incomes of the self-employed persons at any point of time have been split up using overall current ratios (excluding mixed income) between labour and property.²² Percentage share of factors so worked out at the all-India level are used to obtain estimates of the shares of labour and capital (including profit), assuming share of land in these sectors to be negligible.²³ These estimates are given in Table III.5.

²²Uma Datta Roy Choudhury, "Income Distribution and Economic Development in India since 1950-51", The Indian Economic Journal, Vol. 25, No. 2, 1977, pp. 140-164.

²³While for the fisheries sector, it may be presumed that land as such i.e. without any investment has no value importance of land for the forestry sector can not be overlooked, especially when area under forests in the State has increased by 35 per cent between 1960-61 to 1980-81. However, as the land area in the State is increasing not only from economic point of view, but also due to several non-economic reasons, such as, effecting the timely rains, checking the soil erosion, preserving the wildlife, maintaining ecological balance, a precise measure of the share of land in the net income from the forestry sector is not possible. Hence entire non-labour share under this sector is assumed to constitute the share of capital. For area under forest, see, Statistics of Land Utilization in U.P. in Statistical Diary of Uttar Pradesh, Economic & Statistics Division, State Planning Institute, U.P. (different years).

Table III.5 : Factor Shares in Forestry
and Fisheries Sector in U.P.

Years	(Rs. in crore)

In order to obtain factor income estimates for the primary sector, factor-wise income estimates given in Tables III.4 and III.5 have been combined together. Keeping in view the fact that profit in agriculture accrues to the owner cultivator families by way of participation income, profit and wage incomes have been combined together to form the share of labour. Income shares of labour, capital and land in the primary sector have been presented in Table III.6.

Table III.6 : Factor Shares in the Primary Sector (U.P.)

1.3 Factor Shares in the Secondary Sector

The secondary sector comprises of mining, registered and unregistered manufacturing, construction, power, gas and water supply. Except the two sectors mining and construction, where all India percentage shares of factors have been used to work out shares of factors in the State, in all other sectors, shares have been prepared with the help of State level information. Sector-wise availability of data and methodology used for preparing factor shares is discussed below.

1.3.1 Mining : In case of mining sector information available at the State level is rather inadequate. Current and regular statistics available in this sector relates to value of mineral produce only.²⁴ Some stray information about average earnings of workers working under and above mines is also available from Director General of Mines and Safety²⁵ which proves rather insufficient for carrying State level estimation of factor

²⁴ Mineral Statistics of India, Indian Bureau of Mines, Ministry of Steel and Mines, Govt. of India, different issues.

²⁵ Indian Labour Statistics, Labour Bureau, Govt. of India, different issues.

shares under this sector. However, the State being poorly endowed with mineral wealth,²⁶ the contribution of this sector to income of the State is also not very high²⁷ and use of all India percentage shares to work out factor shares in this sector, is likely to make no significant difference in the relative shares of factors in the secondary sector and overall factor shares of the State economy. Factor shares prepared for this sector on the basis of percentage shares of factors at all India level with the help of NAS data have been presented in Table III.7.

1.3.2 Unregistered Manufacturing : Due to the scattered nature of economic activity in this sector, spread all over the rural and urban areas, and prevalence of household enterprises which do not usually maintain income and expenditure accounts, regular statistics under this sector are not collected by any official or private agency.

²⁶ Techno-Economic Survey of Uttar Pradesh, National Council of Applied Economic Research, April 1965, pp.90-97.

of
²⁷ During the entire period/20 years from 1960-61 to 1980-81 percentage share of the mining sector in total SDP has ranged between .09 per cent and .2 per cent only. See, State Income Estimates in Uttar Pradesh, Bulletin No.161, 175 and 199, Economic & Statistics Division, State Planning Institute, U.P.

Only sources of information in this sector are sample surveys carried out by National Sample Survey Organisation (NSSO), the data collected under the centrally sponsored scheme on survey of small scale industries and all India report on the Census of small scale units. NSSO covers only the self-employed households in rural and urban sector.²⁸ The latter two sources also, have a restricted coverage and cover urban areas only. Further, as all these sources provide information with a lag of five to six years, even value added figures in this sector are prepared by moving forward the benchmark estimates, with the help of different indicators.

Besides all the data constraints which render estimation of value added and factor income estimates under this sector difficult, the value added per worker approach used for preparing income estimates creates

²⁸ However in its 29th round the NSSO has covered all the 'manufacturing units' not registered under the Indian Factories Act 1948. See,

(i) Tables with Notes on Survey of Self-Employed Households in Non-agricultural Enterprises, July 1974-June 1975, Report No. 280/3, 29th Round, NSSO, Aug. 1978.

(ii) S. Banerjee and P.K. Basak, "Survey Design for an Enquiry on Self-employment in Non-agricultural Enterprises, NSS 29th Round", Sarvekshana, Vol. 11, No. 4, April 1979, p. 135.

further problems in preparing factor income estimates for, a significant proportion of the output in this sector originates in the self-employed own account enterprises where ownership of all the factors of production rests with the family firm. In such a case, split-over of value added, according to the services rendered by factors in generating output, becomes difficult.

Unlike other sectors, in this sector, the share of capital has been obtained first, and the share of labour has been obtained thereafter as a residual.²⁹ In order to work out share of capital, the value of capital stock in this sector for 1974-75 has been obtained from the NSS 29th Round.³⁰ To obtain capital stock figures for other years, capital-output ratio for 1974-75 has been moved to other years on the basis of index of capital output ratio in the registered manufacturing sector of the State. Main assumption

²⁹ For all the years, share of labour has been obtained by subtracting the share of capital from the estimate of net value added in this sector.

³⁰ "Tables with Notes on Survey of Self-employed Households in Non-agricultural Enterprises, July 1974-June 1975", op. cit.

underlying this exercise is that during the reference period 1960-61 to 1980-81, capital-output ratios in the unregistered manufacturing sector move parallel to the capital output ratios in the registered manufacturing sector of the State (for details see Chapter V of the thesis). With the help of capital-output ratios and the net value added figures, capital stock figures for other years are worked out.

In the absence of any reliable information on the rate of interest on capital in this sector, a notional rate of 15 per cent per annum, same as the average current rate of interest, has been applied to evaluate the income from capital stock.

1.3.3 Registered Manufacturing : In case of organised manufacturing, share of labour has been prepared with the help of ASI data which provides annual figures of wages and salaries and other emoluments paid to labour. However as ASI data includes - power, water supply and some service industries like sanitation also, due care has been taken to exclude them while preparing share of labour for the registered manufacturing sector. Care has also been taken to account for the non-responding units under ASI.

Since complete reports of ASI covering both the Census and sample sectors in the State are available from 1967 only, for earlier years information available from ASI Census sector and NSSO reports for the sample sector has been pooled. Share of capital for all the years, has been obtained as residual after subtracting share of labour from the value added figures, prepared by Economic and Statistics Division, SPI, Lucknow. Estimates so prepared have been shown in Table III.7.

1.3.4 Construction : The sector is badly equipped with statistics needed for preparing broad economic aggregates like factor shares and value added. Acute shortage of relevant statistics in this sector is obvious from the fact that this is the only sector where expenditure approach is used for preparing income estimates, while in all other sectors of the State economy either production or income methods are used. Although, the sector has a wide coverage and includes the construction activities of the Central and the State Governments, their departmental and non-departmental enterprises, local bodies and the private

sector; but information on compensation to employees interest etc. is not available for many of these agencies. Even figures of total expenditure on construction are not readily available for many departmental and non-departmental units of the Central Govt. Such as Railways, Post and Telegraph and the Life Insurance Corporation, which do not provide state-wise break-up of the construction work for projects extending across the State boundaries.³¹ In case of the household sector, no regular statistics, official or unofficial, relating to the construction work is available either for rural or for urban areas in the State. Due to these problems, it has been presumed that factor income shares in this sector would be largely the same as all-India. Estimates prepared for this sector on the basis of percentage share of factors worked out from NAS data for the national economy have been presented in Table III.7.

³¹D.N. Chaturvedi, "Problems of Estimating Gross Fixed Capital Formation at the State Level" in the Journal of Income and Wealth, Vol.4, No.1, January 1980, pp.23-25.

1.3.5 Power, Gas and Water Supply : The Principal Organisation in the Electricity sector in the State is U.P. State Electricity Board (UPSEB). Besides the Board, there were also some municipalities which generated and distributed power upto 1976-77. Some private companies are also working in the sector. Share of labour has been estimated for the Board, municipalities and companies separately and added together to form the share of labour in this sector. Data for preparing labour's share in case of UPSEB have been obtained from its Annual Accounts for all the 20 years of the study. However, in case of companies and municipalities, information on wages and salaries and other benefits etc. for the State were not available. These have been estimated from the all India information in this respect available from the Annual Reports of the Central Electrical Authority of India. For this purpose, value added by municipalities and companies in the country was worked out following income approach. Value added in the State was then obtained as forming same percentage of value added as the percentage of share of energy sold in the State

in the total energy sold by these companies and municipalities in India. Share of labour in value added for municipalities and companies in the State has then been worked out (using same percentage as all India).

In case of water supply, share of labour has been worked out on the basis of ASI data. Share of labour in electricity and water supply (production of gas in the State being negligible) have been added for all the years. Same have been subtracted from the value added figures for this sub-sector to find out the share of capital.

Estimates of power, gas and water supply sector alongwith shares in other sub-sectors of the secondary sector have been presented in Table III.7.

1.4 Factor Shares in the Tertiary Sector³²

The tertiary sector includes transport, storage and communication, trade, hotels and restaurants, banking

³² In preparing factor income estimates for the tertiary sector, the subsector real estate and ownership of dwellings falling under this sector has been excluded. Exclusion has been made due to the problems associated with obtaining reliable estimates of capital stock under this sector. For details see Chapter V of the thesis.

Table III.7 : Factor Shares under Different Sub-Sectors in the Secondary Sector

(in crore Rs)

P E R I O D	Mining		Construction		Unorganised Manufacturing		Organised Manufacturing		Power, Gas & Water supply	
	Labour	Capital	Labour	Capital	Labour	Capital	Labour	Capital	Labour	Capital

and insurance, public administration and other services. In all these subsectors comprising the tertiary sector, shares have been worked out assuming the same percentage shares for different sub-sectors as in case of all India obtained from NAS. Shares of different sub-sectors so worked out are added separately for labour and capital to obtain the factor income estimates for this sector presented in Table III.8.

Table III.8 : Factor Shares in the Tertiary Sector (U.P.)

³³ Absolute share of land in the SDP (excluding real estate and ownership of dwellings) is assumed to be the same as in the primary sector.

Section 2 : Trends in the Relative Movement of
Factor Shares

2.1 Analysis of Trends

This section is devoted to an analysis of the trends in the relative movements of factor income shares during the period 1960-61 to 1980-81. For the purpose of ascertaining the trend, average percentage shares of factors under different time periods, are worked out and presented in Table III.10.

Table III.10 : Average Percentage Shares of
Factor; in Net Value Added :
All Sectors

Periods	(at current price)		
	Labour	Capital	Land
I. 1960-61 to 1967-68	63.01	16.78	20.21
II. 1967-68 to 1974-75	60.62	17.20	22.19
III. 1974-75 to 1980-81	64.95	18.68	16.37
IV. 1960-61 to 1970-71	61.01	17.36	21.63
V. 1970-71 to 1980-81	63.80	18.34	17.86
VI. 1960-61 to 1980-81	63.19	18.10	18.70

Source : Table III.9.

Table III.10 shows a mildly increasing trend in the relative share of capital. Not-with-standing minor increase or decrease in the percentage share of labour during different time periods, its share during 1960-61 to 1980-81 is broadly the same as during 1960-61 to 1967-68 and during 1970-71 to 1980-81. This rather sticky share of labour over the two decades, suggests the 'constancy of labour share', a preposition discussed widely in economic literature.³⁴

Percentage share of land, except for a rise during 1967-68 to 1974-75 over 1960-61 to 1967-68, depicts a decreasing trend throughout.

³⁴ Statistical investigations by A.L. Bowley, E.H. Phelps Brown and P.E. Hart, and Colin Clark for the U.K. contributed to the view that share of labour in the national income remained stable over long periods. Kuznets study for the USA also confirmed that during 1907 to 1940 there occurred no remarkable change in the share of income going to labour, see :

(i) A.L. Bowley, The Change in the Distribution of National Income 1880-1913 in A.L. Bowley and Sir J. Stamp, Three Studies on the National Income, London, 1938.

(ii) E.H. Phelps Brown and P.E. Hart, "The Share of Wages in National Income," Economic Journal, June, 1952.

(iii) Colin Clark, National Income and Outlay, London, 1957.

(iv) S. Kuznets, Long-term Changes in the National Income of the United States of America since 1870, in S. Kuznets and R. Goldsmiths, Income and Wealth of the United States : Trends and Structure, Income and Wealth Series II, Cambridge, England, 1952.

Since changes in relative movements of income shares in the State economy (all sectors) occur due to changes in relative movements of income shares at the sectoral level, the analysis has been extended to broad sectors also. Table III.11 presents percentage share of factor incomes in the net output originating in the primary sector.

Table III.11 : Average Percentage Distribution of Factor Incomes : Primary Sector

Period	Labour	Capital	Land
I. 1960-61 to 1967-68	55.85	12.28	31.87
II. 1967-68 to 1974-75	50.77	13.72	35.51
III. 1974-75 to 1980-81	54.32	15.11	30.56
IV. 1960-61 to 1970-71	52.54	12.83	34.63
V. 1970-71 to 1980-81	53.00	14.99	32.01
VI. 1960-61 to 1980-81	52.77	13.91	33.32

Source : Table III.6.

A comparison of Table III.11 with Table III.10 reveals a close correspondence between the relative movement of shares in the primary sector and the aggregate economy. The reason lies in the fact that the sector weighs heavily both in terms of income and employment. This is evident from the fact that in 1980-81 share of this sector in State income (at current prices) was 50.03 per cent. Its share in total employment worked out to more than 75 per cent.³⁵

Table III.11, like Table III.10 depicts a neat increasing trend in the share of income going to capital. Despite a decline of 5.12 per cent in the relative share of labour during 1967-68 to 1974-75, the share has almost regained its relative position in the subsequent period i.e., 1974-75 to 1980-81. Average percentage shares of labour worked out for the two decades, also reveal that, barring a marginal increase during seventies, the share has remained almost unchanged over the

³⁵ See, State Income Estimates, Bulletin No.199, op. cit., and Census of India 1981, Series 21 (U.P.), Part II, Special Reports and tables based on 5 per cent sample data.

period 1960-61 to 1980-81. Thus, primary sector also supports the constancy of labour share through time.

Though there has been a significant increase in the income share occurring to land during 1967-68 to 1974-75 compared to the earlier period (1960-61 to 1967-68), a declining trend is apparent from the Table III.11. The rather abrupt increase in the relative share of land during 1967-68 to 1974-75, has caused a decline in the relative share of labour during the same period, and has also left its impression on relative changes in income shares for the aggregate economy. For this some explanation seems necessary.

Relative changes in shares of labour and land can occur due to changes in relative growth rates in these inputs and relative changes in their prices. Available number of workers in 1961 and 1971 Censuses are not comparable due to the definitional changes and can not be used as such to measure the growth of labour input. An exercise to make the two Census concepts comparable yields 1.30 and 1.33 as average compound growth rates of the number of workers during 1960-61 to 1967-68 and during 1967-68 to 1974-75

respectively.³⁶ Average growth rates in net sown area (including current fallow land) work out to .76 and -.12 per cent for the two periods respectively. Even if the negative growth rate is discarded as being due to some casual factor effecting the net sown area figures for the terminal year only, the fact that growth in land area was quite slow during the period 1967-68 to 1974-75 can not be ignored. Thus, in spite of a slow growth in land area during 1967-68 to 1974-75 in comparison to the rate of growth in the working force during this period, a change of 3.84 per cent in the share of income going to land points to the steep rise in land values during this period in comparison to the earlier period.

A study of relative price movement is difficult in the primary sector. Since land has no regular market of sale and purchase, a precise measure of appreciation in land values is not possible. In fact, land values appreciate fast due to investment in land and increased demand for food resulting from high population pressure. However, if one takes irrigation as one of the factor

³⁶ See Chapter IV of this thesis.

that increases productivity of land and causes land values to rise fast, it is seen that the index of gross irrigated area as percentage of gross sown area has shown a greater increase during 1967-68 to 1974-75 as compared to 1960-61 to 1967-68 and also 1974-75 to 1980-81 as shown in Table III.12.

Table III.12 : Index of Gross Irrigated Area as Percentage of Gross Cropped Area in U.P.

Period	Index	Percentage change over previous period
I. 1960-61 to 1967-68	100.00	-
II. 1967-68 to 1974-75	142.42	42.42
III. 1974-75 to 1980-81	174.38	22.44

Source : Agricultural Statistics of Uttar Pradesh, Directorate of Agricultural Statistics, Lucknow, various issues.

This perhaps provides some rough explanation as to the relative increase in the income share going to land during period II i.e., 1967-68 to 1974-75 causing a relative decline in the share of labour during the

period and decrease in the share of land in period III,, and a corresponding increase in the share of labour.

A falling trend in the relative share of income going to land in the period 1970-71 to 1980-81, reflects that the nature of technological change during this period has been land augmenting.

In order to assess the trends in the relative movement of factor shares in the secondary and tertiary sectors, relative shares under different time periods have been presented in Table III.13.

Table III.13 : Average Percentage Distribution of Functional Income in the Secondary and Tertiary Sector

Period	S E C T O R S			
	Secondary		Tertiary	
	Labour	Capital	Labour	Capital
I. 1960-61 to 1967-68	77.72	22.28	74.50	25.50
II. 1967-68 to 1974-75	75.53	24.67	78.05	21.95
III. 1974-75 to 1980-81	78.42	21.58	76.43	23.57
IV. 1960-61 to 1970-71	74.43	25.57	75.44	24.56
V. 1970-71 to 1980-81	78.16	21.84	76.95	23.05
VI. 1960-61 to 1980-81	77.31	22.69	76.43	23.57

Source : Tables III.7 and III.8.

Table III.13 shows that the pattern of change in the relative shares of labour and capital during the three sub-periods between 1960-61 and 1980-81 is the same in the secondary sector as observed in the primary sector i.e. labour losing its relative share to capital during 1967-68 to 1974-75 in comparison to the earlier period, and then again regaining it in period III so that relative percentage share of labour during the I and III periods are nearly constant. While decadal percentages worked out, exhibit an increasing trend,³⁷ relative share of labour during 1960-61 to 1980-81 is not significantly different from its average relative share during 1970-71 to 1980-81. Thus it can be concluded that, by and large, there has been no marked change in the share of labour during the two decades.

The pattern of movement in the relative income shares during Periods I, II and III in the tertiary

³⁷ An analysis of the factors behind this increasing trend requires a detailed study of relative changes in different sub-sectors of the secondary sector such as organised and unorganised manufacturing, power etc. Limitations of time and data, do not permit such an analysis for the purpose of the present study. However, a general explanation can be given in terms of employment and earnings both of which have increased very fast during the decade 1970-71 to 1980-81 compared to the decade 1960-61 to 1970-71.

sector is different from the pattern of relative share movement observed in the secondary and primary sectors during these periods. For, while in both the sectors primary and secondary, relative share of labour shows a decline in Period II (1967-68 to 1974-75) in comparison to Period I (1960-61 to 1967-68), and a rise in Period III (1974-75 to 1980-81) as compared to Period II; in the tertiary sector relative share of labour has increased during Period II in comparison to Period I, and has declined in Period III in comparison to Period II. Despite all this, it is interesting to note that average percentage relative shares worked out for the two decades and for the period 1960-61 to 1980-81 do not reveal any substantial change.

2.2 Conclusions

Main conclusions emerging from the analysis of the relative movement in factor income shares in the economy during 1960-61 to 1980-81 can be summarised as :

1. By and large, the relative share of labour has remained constant at a level of nearly 63 per cent during the two decades, supporting the 'constancy of labour share' hypothesis.

2. The relative share of capital shows a mild increasing trend throughout the period.
3. Share of land is large relative to the share of capital all along. Share of land however shows a declining trend during the latter decade i.e. 1970-71 to 1980-81.
4. Pattern of movement in the relative income shares in the primary sector is the basic determining factor of relative changes in income shares at the economy level.
5. Relative share of labour, both in the secondary and tertiary sectors, is large in comparison to its relative share in the primary sector. Both the sectors, while supporting constant share hypothesis by and large, exhibit a mild increasing trend in share of labour which is more pronounced in the secondary sector than in the tertiary sector. In comparison to these two sectors, percentage share of labour has been more sticky in the primary sector.

Appendix B

The purpose of this note is to provide some details of the FMS data covering two districts Deoria and Muzaffarnagar used for the preparation factor income estimates for the entire State.

Studies in the economics of Farm Management in Deoria and Muzaffar Nagar included following crops :

<u>Deoria</u>	<u>Muzaffarnagar</u>
1. Paddy	1. Paddy
2. Wheat	2. Maize
3. Sugarcane	3. Wheat
	4. Gram
	5. Peas
	6. Sugarcane

Factor shares have been prepared for all the six crops included in FMS (Muzaffarnagar). For those crops which were common in both the studies i.e. Deoria and Muzaffarnagar factor shares have been prepared by averaging the cost figures (per hectare) in the two studies. Break-up of the input cost per hectare for the six crops as obtained from the two studies for each of the three years, 1966-67, 1967-68 and 1968-69 has been shown in Tables B.1, B.2 and B.3 respectively.

Table B.1 : Input Costs per Hectare (1966-67)

(in Rs)

Crops	Wages	Interest	Rent	Intermediate inputs	Total cost
Paddy	132	69	380	296	871
Maize	97	89	389	236	811
Wheat	147	82	382	485	1096
Gram	108	88	472	352	1034
Pea	113	89	474	1362	1038
Sugarcane	378	132	393	794	1697

- II) Studies in the Economics of Farm Management in Muzaffarnagar District, Uttar Pradesh, Combined report 1966-69, Directorate of Economics and Statistics, Government of India, 1975.

Table B.2 : Input Costs per Hectare (1967-68)

(in Rs)

Crops	Wages	Interest	Rent	Intermediate inputs	Total cost
Paddy	184	80	422	254	940
Maize	124	85	545	162	916
Wheat	162	93	436	490	1181
Gram	76	69	543	236	924
Pea	70	67	437	232	952
Sugarcane	405	138	504	773	1820

Source : Same as Table B.1.

Table B.3 : Share of Labour, Capital and Land in Total Cost

(in Rs)

Crops	Wage	Interest	Rent	Intermediate inputs	Total cost
Paddy	196	83	357	345	981
Maize	112	92	428	271	903
Wheat	161	88	353	646	1248
Gram	76	82	450	334	942
Pea	67	86	439	304	896
Sugarcane	382	144	503	879	1907

Source : Same as Table B.1.

In order to judge the reliability of these factor income estimates obtained on the basis of FMS data it seemed worthwhile to compare these figures with some other studies in the State. Fortunately one farm management survey report for the year 1968-69 carried out by Economic & Statistics Division, State Planning Institute (hereafter referred as SPI study) was available for this purpose. The study was conducted in four districts of the State - Faizabad, Gonda, Bulandshahr and Moradabad which are representative of eastern and

western regions of the State. Total cost per hectare for five major crops in the study has been shown in Table B.4.

Table B.4 : Total Cost Per Hectare of Major Crops in the SPI Study

(In Rs)	
Crops	Total Cost per Hectare
Paddy	626
Maize	466
Wheat	994
Pea	563
Sugarcane	1522

Source : Krishi Utpadan Ki Sanshipta Roop Rekha 1968-69, (Hindi), Economic and Statistics Division, State Planning Institute, U.P.

A comparison of the above figures with the figures of total cost given in Table B.3 shows that cost figures in the SPI study lie constantly below the figure given by FMS study. The differences are too large to accept. A closer investigation into the concepts used by SPI study revealed that the study did not include imputed value of owned land. Excluding rental value of owned land from the FMS total cost figures, we find that total cost figures become comparable in the two studies (Table B.5).

Table B.5 : Total Cost Excluding Rental
Value of Owned Land

Crops	(In Rs)	
	SPI Study	FMS Study
Paddy	626	656
Maize	466	486
Wheat	994	915
Gram	-	8
Pea	563	468
Sugarcane	1522	1426

Source : Col.1 - SPI Study

Col.2 - FMS (Muzaffarnagar and Deoria).

While figures of the total cost in the two studies now do not reveal large variations, yet their exist large variations in the share of labour in total cost in the two studies. Percentage and absolute share of labour in the two studies have been shown in Table B.6.

Table B.6 : Percentage* and Absolute Share of Labour in Total Cost

Crops	SPI Study		FMS Study	
	Share of labour	Total Cost	Share of labour	Total cost
Paddy	262 (42)	626	196 (30)	656
Maize	203 (44)	466	112 (23)	486
Wheat	239 (24)	994	162 (18)	915
Pea	154 (28)	562	67 (15)	463
Sugarcane	411 (27)	1522	382 (27)	1426
All Crops	1269 (30)	4170	919 (23)	3946

Source : See the text.

* figures in parentheses represent percentage in total cost.

Table B.6 shows large variations in the share of labour in total cost in the two studies : strangely enough for all the crops except sugarcane in which both the studies allocate same 27 per cent share of total cost to labour, share of labour in FMS lies constantly below the share of labour given in SPI study. If we include rental value of owned land in the total cost of FMS study share of labour becomes all the more lower as shown in Table B.7.

Table B.7 : Share of Labour in Total Cost
(including rental value of owned
land) in FMS Study

Crops	Total Cost (in Rs)	Absolute share of labour (in Rs)	Percentage share of labour
Paddy	981	196	20
Maize	903	112	12
Wheat	1248	162	13
Pea	942	67	8
Sugarcane	1907	382	20
Total	5981		

Source : See the text.

Since both the studies have used same basis for evaluation of family labour and hired labour, differences in labour share in total cost in the two studies were difficult to explain.

A careful study of the SPI study revealed that some portion of the area sown under wheat, paddy, maize and pea, was under-mixed cropping. The study also asserted that in the absence of any scientific method of allocation of area under mixed cropping total crop cost

incurred in crop production were assumed to be for the principal crops. Thus it is expected that labour input per hectare on these crops might have gone up especially in the case of small holdings on which mixed cropping^{is} generally practiced. Saini¹ also observes that crop mixing on small farms tends to increase labour use per hectare. This also explains the reason as to why the share of labour in case of sugarcane came out to be the same in the two studies (for no crop was mixed with sugarcane in the SPI study).

In the absence of any other study which could provide some evidence for the share of labour in total cost we have no other alternative than to accept the figures given by FMS. We have rejected SPI study as it over-estimates the share of labour and also provides no information about the shares of other two factors of production - namely capital and land which have been grouped in the study under "other miscellaneous expenditures". Another and perhaps more strong justification

¹G.R. Saini, Farm Size Resource Use Efficiency and Income Distribution, Allied Publishers Pvt. Ltd., Delhi, 1979, p.116.

for rejecting the SPI study in favour of FMS is that SPI study relates to a single point of time and due to heavy dependence of agriculture on monsoon and wheather conditions in the State, the estimates are likely to give biased results if the year during which the study had been conducted happened to be abnormal. FMS data on the other hand, has greater claim for reliability (being based on cost accounting method) and provides figures for three consecutive years, average of which can be satisfactorily used to ascertain the trend in the movement of factor shares over-time, which is our primary objective.

Appendix 31

This methodological note describes the procedure of preparing factor shares for crop production in the State. In preparing these shares, our practice has been to multiply per hectare estimates of different factors for various crops included in FMS and comprehensive scheme by the area under those crops in the State. For the crops for which per hectare estimates were not available, average per hectare estimates of the available crops have been multiplied by the area covered by those crops (i.e. area covered by the crops other than those included in FMS or comprehensive scheme).

For each of the year 1966-67, 1967-68 and 1968-69, we have first calculated per hectare shares relating to each factor land labour and capital for the six crops with the help of FMS Muzaffarnagar and Deoria (see Tables B.1, B.2 and B.3). These per hectare factor estimates have then been combined by using as weights area under each of the six respective crops. Total so arrived gives estimated shares of land, labour and capital for the six crops in the respective years. For

the area covered by the crops other than the six crops in the State, per hectare estimates of factor incomes obtained as an average of the per hectare estimates of the six crops, have been multiplied by the total area covered by other crops in the State. Two sets of estimates have been added together to get the total factor estimates for the State.

While by the above exercise we have been able to prepare factor estimates for the years 1966-67, 1967-68 and 1968-69, non-availability of comparable data prior to 1966-67 posed difficult problems for calculating factor estimates for the period 1960-61 to 1965-66. There appeared to be two ways to overcome this problem - one was to assume that for the years prior to 1966-67 percentage share of the three factors in the value added was the same as during late sixties. The other way was to obtain with the help of some indicator or with the help of some studies, percentage change in respect of each factor that has taken place during the period. Fortunately we could get one FMS conducted by DES* in Merrut

* Directorate of Economic and Statistics, Ministry of Agriculture, Govt. of India.

and Muzaffarnagar districts of Uttar Pradesh during 1954-57. Both districts in the study being in the western region, results of this study compare reasonably well with the results obtained from FMS Muzaffarnagar. By comparing the two studies, we have first calculated total percentage change in factor shares during 1954-57 to 1966-67 in the western region of the State. There being no study which could indicate percentage change in factor shares in the eastern region of the State during the same period, we have assumed that magnitude of total percentage change in the eastern region would be the same as in the western region. This, along with one more simplifying assumption, that the total change in per hectare shares during 1954-57 to 1966-67 was distributed uniformly over the years, has helped us to prepare per hectare estimate of factors during 1960-61 to 1965-66. Multiplying these by total area sown in these years, factor estimates for each year have been obtained.

The year 1966-67 has been purposively selected to compare with the average obtained for the period 1954-57 (instead of comparing 1954-57 average with 1966-69

average) because the year 1966-67 marked a turning point in the State's agriculture, being the year during which new agricultural technology using HYV was introduced in the State. As application of this new agricultural technology started yielding results, by 1967-68, it appeared more logical to presume that factor shares before 1966-67 i.e. from 1960-61 to 1966-67 would be more inconformity with trends and changes that have occurred between 1954-57 to 1966-67.

While the two assumptions mentioned above, helped us to estimate per hectare factor estimates during 1960-61 to 1965-66 in case of labour and capital, estimate for the third factor i.e. land could not be made, as FMS (1954-57) did not include the rental value of owned land. In order to obtain absolute share of land in the value added per hectare, estimate of land in 1966-67 has been moved backward with the index of gross value of agricultural output and total area sown in the State during years.

For the period 1975-76 to 1977-78 factor shares have been prepared by using the data as available under the comprehensive scheme. The crops considered

for this purpose are paddy, wheat, sugarcane and barley. Inclusion of crops and selection of years has been guided primarily by the availability of data. Factor shares for the years 1975-76, 1976-77 and 1977-78 have been prepared, using the same procedure as for 1966 to 1969. Wherever data in respect of any crop for any year were not available, average of the two years or figures of the latest year as relevant have been used.

For filling the gaps in the estimates of the factor shares between 1968-69 and 1975-76 we have used the same technique and same assumption as we did in period I, i.e., finding the total change in factor estimates between 1966-69 (3 years average) and 1975-78 (3 years average) and distributing it uniformly over the years.

For the remaining three years i.e. 1978-79, 1979-80 and 1980-81 information regarding all the four crops was not complete. Figures of the latest relevant year have been used to fill the gap.

Appendix B₂

METHODOLOGICAL NOTE

The farm management studies Deoria and Muzaffarnagar provide gross and net maintenance cost along with its different components per cow and per she-buffaloe. On the basis of these studies labour and capital component (i.e. value of labour and capital used in maintenance per cow and per she-buffaloe), has been worked out for each of the three years 1966-67, 1967-68 and 1968-69.

In order to estimate the value of labour used in milk production, labour cost per cow and per she-buffaloe as available for each year 1966-67, 1967-68 and 1968-69 have been multiplied, by the number of milched animals over 3 years in milk, in the corresponding years. For the years prior to 1966-67 and after 1968-69, labour charges per milched animal obtained by taking average of the three years (1966-69), have been moved forward and backward with the help of relevant indicators.

The choice of the type of indicator used for the above purpose has been guided primarily by the factors that are expected to bring about changes in the total value of labour used in the upkeep of milched cattle in the State. These changes may occur on account of the following factors.

1. A change in the technology of upkeep of milched cattle.
2. Changes in the composition of population of livestock i.e. changes in the proportion of milched animals in the total population of cows and buffaloes.
3. Changes in the cost of acquisition of human labour brought about by changes in the wage rates of labour engaged in the upkeep of milched cattle.

As for the first, there is little evidence that the technology of cattle rearing has undergone any significant change during the period of our study mainly due to the fixed nature of work performed by human labour such as grazing, feeding, milching, cleaning and others. Thus, it appears reasonable to assume, that the amount of labour used in these activities would not change to any significant amount, unless there is some major change involving use of some mechanical devices which may substitute for labour in these activities. Such a major change during 1960-61 to 1980-81 is hard to conceive for a

backward agrarian economy like Uttar Pradesh.

Changes in the number of milched animals which bring about changes in the total labour component in milk production are taken due care of, by interpolating the bench mark estimates of the number of milched animals of the relevant category. As interpolation is based on the assumption of constant geometric rate of growth, the yearly figures arrived at may suffer from over-estimation or under-estimation on this account. As changes in the value of labour used in milk production are also expected to occur on account of changes in wage rates of labour used in these activities, the human labour component per cow and per she-buffaloe obtained as an average of the three years, . . . have been moved to other years with the help of index of wages of other agricultural labour.

Estimates of Interest in the Milk Production

The FMS Muzaffarnagar and Deoria, give interest charges paid per cow and per she-buffaloe. While FMS Muzaffarnagar gives interest paid on fixed as well as

working capital, the FMS Deoria gives interest paid on fixed capital only. As working capital in animal husbandry is usually paid within the month or so, account has been taken of the interest paid on fixed capital only. Thus interest paid per cow and per she-buffaloe in the two studies, have been averaged separately to obtain the interest paid per cow and per she-buffaloe during 1966-67, 1967-68 and 1968-69. These have been multiplied by the number of milched animals of the relevant category and the figures so obtained have been added up, to get the estimate of interest for milk production.

For estimating interest in milk production during 1960-61 to 1965-66, we have assumed the percentage change in this sub-sector to be the same as in the case of crop production. The assumption, though not based on any statistical evidence may not be totally false, as milk production and crop production activities are usually carried side by side in the State. This together with the assumption of uniform increase in capital's share over the years, has enabled us to prepare per milched animal capital component during 1960-61

to 1965-66. Same procedure has been adopted to prepare capital estimate for the period 1968-69 onwards. Estimates of share of labour i.e. wages paid, and interest, in case of milk production are given in Table III.2 in the text.

Since FMS provide no information about payment of rent in case of milched animal, the share of land in this sub-sector is presumed to be negligible.

Appendix B₃

In order to estimate labour and capital component in case of non-milk products we have first tried to identify the population of livestock relevant for this purpose. This consists of :

1. Buffaloe males over 3 years not in use for breeding or work.
2. Buffaloe female over 3 years not in use for milk or other purposes.
3. Cattle male over 3 years not in use for breeding or work.
4. Cows over 3 years not in use for breeding or work.
5. Goats
6. Pigs
7. Sheep
8. Poultry

These animals have been converted into the cattle equivalence (milched cow) by using the following percentages of cattle equivalence.

Table B₃ Percentage Cattle Equivalence

Sl. No.	Type of Cattle	Percentage cattle equivalence
1.	Buffaloe in milk and breeding bulls	133.30
2.	Cattle breeding bulls, cows in milk, buffaloe bulls not in work or use	100.00
3.	Cattle bulls not in use, dry cows not in work or use and buffaloe young stock	50.00
4.	Rural buffaloe and bulls for work	133.30
5.	Rural cattle working bullocks, cows for work	100.00
6.	Cattle young stock	33.33
7.	Sheep, goats and pigs	10.00
8.	Poultry	0.50

Animal used in Transport Industry

1.	Urban buffaloes & bullocks for work, horses, ponies and camels	266.70
2.	Urban cattle bullocks and mules	200.00
3.	Donkeys	100.00

Source : Methodology of State Income Estimates
(revised series), op. cit., p.20.

While there may appear an element of over-estimation in considering total livestock population under category 3 and 4, but we presume that over-estimation if any would be offset by the under-estimation caused by not taking into account camels, horses and ponies, which provide bones, hides and skins and hair etc. to the animal husbandry sector.

A precise estimate of the human labour and capital cost, in the production of non-milk products is hard to make, due to the problems associated with a complete identification of the type of animal that contribute to the value of output in the non-milk sub-sector of the animal husbandry sector. This is due to the fact that some animals contribute in other industries also, and it is difficult to find out what proportion of the total cost used in their maintenance should be allocated to the animal husbandry sub-sector for e.g. horse, ponies and camels etc. which are used in the transport industry but who add to the value of animal husbandry after they are dead. In such a case estimation of labour and capital components for this part of the animal husbandry

sub-sector has to be based on some guess work, and to that extent our figures may suffer from some degree of over or under-estimation.

Chapter IV

GROWTH OF LABOUR INPUT IN UTTAR PRADESH

Growth of labour input during a given period of time may be looked upon as a function of (i) changes in the number of working force and in the alteration of their sex-proportion and age-distribution, (ii) changes in the length and pattern of employment due to shift of labour from seasonal to non-seasonal employments, pressure of demand for output or national emergency, or lock-outs, strikes, power break-downs etc, and (iii) due to qualitative changes in labour skill resulting from better training, education and health improvements etc.

1. Choice of Measure

Measuring growth of labour input over different years in a study seeking to analyse the productivity of different factors bristles with problems.

Theoretical considerations call for a standard which not only embodies all these changes, but ensures an accurate measurement of each type of change. An Attempt to evolve such a standard measuring unit does not seem feasible.

For practicable purposes, however, two measures are often used as an index of growth of labour input. They are (i) number of workers, and (ii) man-hours worked. The first concept does not take into account, the time used in the production of total output, and the effects of improvements in the quality of labour, and the second does not take into account, changes in the size and composition of the working force and the contribution of improved skills.

In regard to the first concept it has been mentioned, "the concept of man-hours worked for or more precisely man-hours paid for which includes hours not worked such as reporting time, rest periods, sick-leaves, holidays and paid voccations provide a more useful measure of labour time required for production within the existing institutional framework. They also signify the gross amount of labour that must be purchased for continued production".¹

¹ Kehar Sangha, Productivity and Economic Growth, Asia Publishing House, London, 1964, p.19.

But, the choice of a particular concept for the measurement of labour input in any study is guided very much by the availability of data and the relevance of that concept to the socio-economic set up of the region. Hence, despite the merits of 'man hours' concept mentioned above, it could not be used for the purpose of the present study.

Man hours 'worked for' or 'paid for' figures are not available for all the economic activities at the State or national level. Reliable figures are available only for the organised sector. For unorganised sector, data are largely unavailable. Though National Sample Survey Organisation (NSSO) has collected some data on 'hours worked' in a week in the agricultural sector, in its twenty-seventh and thirty-second rounds, but the concept of 'man hours worked' used by NSSO is unrealistic and meaningless due to the unstandardised nature of farm operations and lack of clarity in the conception of hours among the rural workers.² Not

²J.N. Sinha, "Some Methodological Aspects of Employment" in Population Statistics in India, A. Bose, D.B. Gupta and G. Ray Choudhury (eds.), Vikas Publishing House, New Delhi, 1977, p.113.

only in the farm sector, but in other unorganised activities also, data on labour time disposition are neither available nor relevant. This is because production in this sector is scattered over a large number of family based enterprises which usually do not hire labour. All members of the family share the work in varying degrees and all enjoy family income. In such cases, due to lack of a well established relationship between income and the work-load, and the work spreading habits of the self-employeds, a precise count of labour time in economically productive work, can hardly be made on any scientific basis.³ It has therefore been argued that "the 'time' criterion is the legacy of the 'labour-force' approach borrowed from the industrialised countries. It has but limited relevance for a part of the labour market where the work intensity per unit of time as well as the productivity and the labour's remuneration related thereto are standardised".⁴

³ "for hired casual labour, time disposition data in terms of standard days or hours are more meaningful. But for the self-employed, even the most precise count of labour time spent in different activities may at times be misleading...when there is not much work the self-employed workers may reduce the intensity of work effort but spread it over the whole day or week...the survey investigator will count it as a full day or week worked..... In serious cases of this sort, time measures of employment fail, and we may have to resort to more indirect measures with pre-specified norms of productivity or consumption", Pranab K. Bardhan, Land, Labour and Rural Poverty : Essays in Development Economics, Oxford University Press, Delhi, 1984, p.37.

⁴ J.N. Sinha, "Some Methodological Aspects of Employment" in Population Statistics in India, op. cit, p.113.

In the absence of requisite data we have decided to use the second concept viz. the 'number of workers' as an index of labour input. Denison has also favoured use of this concept as it is not effected by changes due to shortening of 'man-hour' per week, which is likely to effect labour input per hour.⁵ The choise of 'number of working force' seems apt to U.P., the most populous State of the Indian Union, and one of the most economically backward and poverty ridden area. For such a State, containing a vast force of unemployed increase in the numbers in the working force can be a meaningful determinant of economic growth.

Having decided to use the number of workers as an index of labour input, our next step is to look for the sources of data for this purpose. Although it is desirable to use current data on employment to measure annual changes in the estimates of the working force, such data for all sectors are not available. The only choice left is to rely on Census data, which is on decadal basis. Fortunately, our study period is completely covered by the three Censuses 1961, 1971 and 1981

⁵E.F. Denison, Sources of Economic Growth in the United States and the Alternatives Before Us, Supplementary Paper No. 13, Committee for Economic Development, New York, 1962, p.36.

1961 and 1981 coinciding with the extreme points of the study period.

Before any use of Census data is made, it is better to point out that "the term working force refers to the number of persons engaged wholly or partly in the production of goods and services".⁶ Measurement of the working force at any point of time, depends on a careful identification of the number of persons who actually contribute in the production of goods and services at that point of time. The problem of successful identification is handicapped by several conceptual difficulties in case of typically underdeveloped economies, where a bulk of production originates in family firms. As work is shared by members of the family, but not on strictly commercial basis, no regularity of time or wage is required. In such cases domestic and economic duties get intermixed, and it becomes difficult to distinguish persons, who perform economic duties and those, who do not. All appear employed, a sort of full employment prevails, and the problem of identifying those who

⁶ National Account Statistics : Sources and Methods, Statistical Organisation Department of Statistics, Ministry of Planning, Government of India, April 1980, p.57.

might actually be called effectively employed, lends itself into the problem of measurement of disguised unemployment. As every one would consider himself actively participating in economic activity, the hypothesis of excessive labour use leading to zero, or to very low marginal product of labour, has often been advanced.⁷ Even if it is assumed that the hypothesis does not hold true (as there are controversies attached to the hypothesis⁸), one can not certainly escape the problems of a clear distinction between those who participate effectively, and those whose participation may only be called marginal, unless, as Bardhan observes, "Some prespecified norms of productivity or consumption"⁹ are set up.

⁹Pranab K. Bardhan, Land, Labour and Rural Poverty, op. cit, pp.30-33.

As no such standard norms of productivity have yet been evolved, the problem of bringing within its purview all those who might be considered as economically active, has led the Census authorities (since 1961) to experiment with different concepts and definitions of worker. In consequence, the estimates of the working force thrown up by these Censuses remain largely uncomparable and can lead to misleading conclusions, if not used with extreme caution. When the purpose is to measure the growth in the working force during a specified time period, it is essential to ensure that strict consistency and comparability in the concept once adopted, is maintained throughout.¹¹ Hence in what follows, an attempt has been made to highlight the effects of changes in the concept and

definition of worker in the three Censuses. An exercise to bring them to a comparable form has been made in the next section.

2. Changes in the Concepts and Definitions of Worker

While every Census since 1961 adopted 'activity status' or labour force approach for including or excluding any person in or from the work force, the very criteria of ascertaining a person's activity status has changed from one Census to the other. As a result, marked deviations were noticed in the work participation rates both in the State and at the all India level. Work participation rates in the three Censuses are set out in Table IV.1.

Table IV.1 : Worker Participation Rates (UP)¹²

Years	Persons	Male	Female
1961	39.12	58.19	18.14
1971	31.14 (30.94)	52.28 (52.24)	7.10 (6.71)
1981	30.80 (29.13)	51.50 (49.60)	9.52 (5.39)

Sources¹³ : C i) Census of India, U.P., 1961, Part II-B(ii) General Economic Tables, (ii) Census of India, U.P., 1971, Part-II-B(ii) General Economic Tables, (iii) Census of India 1981, Series 22 U.P., Primary Census Abstract.

¹² Figures in parentheses are work participation rates for principal workers in 1971 and main workers in 1981.

¹³ Hereafter referred as Census of India, UP 1961, 1971 and 1981 only.

The worker participation rates reported by 1961 Census are the highest both for males and females (Table IV.1). A fall of 8 per cent in the work participation rates between 1961 and 1971 appears something unusual.

The table further shows that worker participation rates,¹⁴ have improved marginally in 1981, though still lying much below the 1961 level. Neither any theoretical nor empirical evidence supports such a drastic change in the activity pattern of the population. It is true that in developing agrarian economies, work participation rates have a tendency to decline during the early phase of economic development, even then it is difficult to believe that the activity pattern of the population that showed a decline of only 7.4 percentage points during 1911 and 1951, a period of forty years,* would undergo so sudden and drastic change as to lower the worker-population ratio by more than 8 percentage points in a period of a single decade. It only indicates, that the large differences in the WPR reported by 1961 and 1971 Censuses are largely conceptual. Let

¹⁴ Hereafter referred as WPR only.

* See Table IV C given in foot note on page 161.

us therefore look at the concepts and definitions of workers as adopted in the three Censuses.

The 1961 Census adopted economically productive work, as the criterion for including a person in the work force. In case of regular employment, in trade, profession, business service or commerce, a person was to be counted as worker, if he remained employed during any of the fifteen days, preceding the date of enumeration. In case of seasonal work, some restriction upon the entry into the work force was imposed, by setting the criterion of regular work for more than one hour a day, throughout the greater part of the working season. However, this formulation was wide and vague. In the absence of any clarity about the seasonality and regularity of work, the criterion was unaccountably wide, bringing within its ambit any one who has worked, no matter with what usefulness, or with how much regularity.

On the other hand, 1971 Census adopted a rather restrictive approach for categorising a person in the work force. A person was enumerated as worker, if his main activity was participation in any economically productive work. In order to ascertain a person's 'main activity', every person was asked as to how he engaged

himself mostly, during the reference period. In case he spent his major time in economically productive work in the reference period, he was enumerated as a principal worker. In case of seasonal work, the reference period was one year, and in case of regular employment it was one week only.

The 1981 Census adopted a trichotomous classification of workers—main workers, marginal workers and non-workers. A person was enumerated as worker, if he had worked any of the day, during the reference period of last one year. All those categorised as workers, were further recategorised into main and marginal workers. Main workers were those, who worked for major part of the last year i.e. 183 days or more, or at least six months, the rest being termed as marginal workers.

The major time spent criterion used for principal workers in 1971 and main workers in 1981, are nearly the same.¹⁵ As such, principal workers of 1971 and main

¹⁵ Although reference period used for ascertaining a person's main activity differed in 1971 and 1981 Census from working season to whole year in case of seasonal employment, and one week to one year in case of regular employment, these differences are not found to effect the work participation rates to any significant extent. J.N. Sinha has noted that work participation rates obtained from various NSS rounds using different reference periods reveal that fluctuations were not significant. J.N. Sinha, "1981 Census Economic Data : A Note", op. cit, p.196.

workers of 1981, compare fairly well (Table IV.1). However, they do not compare with 1961 Census estimate of workers. Due to the adoption of 'major time spent' criterion in 1971, all those working in economically productive enterprises, but not for most of the time in the year like old persons, students and unpaid female workers, could not find place in the work force. These were probably regarded as workers in 1961 under the liberal criterion of one hour regular work. As most of these workers were rural people, especially the unpaid female labour, incomparability between 1961 and 1971 estimates of workers is more glaring in case of females as revealed by Table IV.2.

Table IV.2 : Work Participation Rates of Males and Females According to Rural and Urban Residence

Years	Male		Female	
	Rural	Urban	Rural	Urban
1961	59.20	51.74	19.90	5.34
1971	52.98	47.85	7.27	3.10
1981	50.17	47.10	5.39	3.58

Source : Census of India, U.P. 1961, 1971 and 1981.

(For 1971 only principal workers and for 1981 only main workers have been considered)

Work participation rates for urban females are comparable for the three Censuses (Table IV.2). However for rural females, work participation rates in 1971 is 12.63 per cent lower than that in 1961, although 1971 and 1981 are comparable (Table IV.2). This shows the possibility of enumerating as worker, unpaid rural females in 1961 who remained outside the work force in 1971, due to adoption of 'major time spent' criterion. However the extent of decline in WPR in 1971 as compared to 1961 is so large, that it can not be attributed only, to the under reporting of secondary activity in 1971.¹⁶ What appears likely is, that the concept of 'main activity' prevented many working females who were spending their major time in economically productive work, from reporting themselves as workers. The social conventions, regarding house keeping as the main activity of the females, especially in rural areas, might be another factor.

¹⁶ Although enumerators in 1971 were asked to report the gainful secondary activity of non-workers but the count of secondary workers is too small and suggests that gainful activity of the non-workers was not enumerated fully (see Table IV.1).

In case of males also, 1961 WPR seems higher both in rural and urban sectors (Table IV.2). Some of the differential increase in 1961 might be due to the small percentage of school going children in 1961 as compared to 1971. To find out whether the differential increase in 1961 was due to enumeration of marginal workers, we have to see if male WPR in those age-groups where marginal workers are likely to be concentrated shows a greater decline in 1971 and 1981 as compared to 1961. Table IV.3 shows work participation rates for rural males in different age groups.

Table IV.3 : Work Participation Rates for Males
According to Broad Age-groups and
Rural-Urban Residence

Age-groups	Rural			Urban		
	1961	1971	1981	1961	1971	1981
0 - 14	9.30	5.82	4.60	3.79	3.23	2.30
15 - 59	94.54	88.59	87.03	83.63	77.90	74.67
60 & Above	88.06	83.26	77.47	65.94	65.84	57.49

Source : Census of India, U.P. 1961, 1971 and 1981.

(For 1971 only principal workers and for 1981 only main marginal workers have been considered).

For all the age groups under study, WPRs in 1971 and 1981 compare fairly well both in rural and in urban areas. However in the age group 0-14 and 15-59 work participation rates for rural males in 1961 seem higher compared to 1971. Though a part of high WPR in 1961 compared to 1971 in the age group 0-14 and 15-59 might be due to the rise in the percentage of school and college going population in 1971 as compared to 1961 but some of it is likely due to enumeration as workers, children and young persons in the age-group 0-14 and 15-59 although they were only marginal workers. Due to the high weight acquired by the age group 0-14 in the total population,¹⁷ any over-estimation of participation rates in this age group is likely to effect overall WPR to a greater extent.¹⁸

In case of urban males also WPR in the age group 15-59 seem higher in 1961 as compared to 1971, showing the likelihood of enumerating marginal participants

¹⁷ According to 1961 Census, percentage share of the age group 0-14 in total population was 40.48 per cent.

¹⁸ Overall work participation rate may be looked upon as the weighted sum of the age specific WPR, weights being the proportion of population in the respective age-groups. B.H. Dholakia, Sources of Economic Growth in India, Goods Companion, Baroda (India), 1974, p.86.

perhaps under 15-25 age group i.e. school-college going population.

3. Comparable Estimates of Workers : Adjustment in 1961 Census Estimates

The above discussion clearly shows that while figures of main workers of 1971 and 1981 are comparable for males and females, in both rural and urban areas, the figures of 1961 Census are not. Hence to get a meaningful idea about the change in the activity pattern of the population, some adjustment in 1961 estimates are required.

While a number of studies suggesting various methods for bringing in comparability in 1961 and 1971 Census estimates are available¹⁹ the method followed in this.

¹⁹ (i) J. Krishnamurthy, "Working force in 1971 Census : Some Exercise on Provisional Totals", op. cit.

(ii) J.N. Sinha, "A Rational View of Census Economic Data", op. cit.

(iii) J.N. Sinha, "1981 Census Economic Data: A Note", op. cit.

(iv) Jaipal P. Ambannavar, "Comparability of 1961 and 1971 Census Data", op. cit.

(v) K.N. Shrinivasan and Des Raj, "Comparability of Data on 'workers' in the 1961 and 1971 Census", op. cit.

study is based on the procedure suggested by the Resurvey²⁰ and adopted by Central Statistical Organisation.²¹

Main assumption underlying the method used here is that, the effect of conceptual difference in the participation rates would be the same in the State, as at the all-India level. Thus, 1961 estimates of workers for different industrial categories in the State have been multiplied by the ratio of actual to adjusted estimates of 1961 in the respective categories, at the all-India level, available from C.S.O. Resulting estimates, are the estimates of main workers in 1961, comparable to the Census concept of 1971 main workers. Sex-wise break up for the adjusted work force in 1961 has been obtained by comparing the work participation rates in different age groups in the 1961 and 1971 Census²² (for methodological details see Appendix C and C₁),

²⁰Census of India, 1971, Report of the Resurvey on Economic Questions - Some Results, Paper No.1 of 1974.

²¹National Account Statistics, op. cit., pp.59-64.

Work participation rates based on the comparable estimates of workers in the three Censuses have been shown in Tables IV.4 and IV.5.

Table IV.4 : Sex Specific Work Participation Rates in U.P. (based on comparable estimates of main workers only)

Years	Male	Female	Persons
1961	54.89	11.28	33.89
1971	52.98	6.71	30.94
1981	50.31	5.39	29.32

Table IV.5 : Work Participation Rates for Male, Females and Persons According to the Rural-Urban Residence in U.P. (based on comparable estimates of main workers only)

Years	WPR in Rural Areas			WPR in Urban Areas		
	Male	Female	Persons	Male	Female	Persons
1961	55.40	12.10	34.62	48.23	5.334	29.02
1971	52.98	7.27	31.48	47.85	3.09	27.67
1981	50.99	5.90	29.72	47.30	2.99	26.99

Source : See the text, Appendix C₁ and Census of India 1961, 1971 and 1981.

It is observed from Table IV.4 that work participation rates in the State are quite low. During the three decades on an average nearly 31.35 per cent of the population has been working and supporting the total population. Also, there are wide variations in the work participation rates in rural and urban areas (Table IV.5). The root cause of such low levels of participation rates in the State is very low participation rates found in the case of females. Female participation rates vary between rural and urban areas, being substantially higher in the rural than in the urban areas. Due to relatively high female participation rates in rural areas, compared to urban areas, overall participation rates in rural areas are also higher as compared to urban rates.

A declining trend is observed in work participation rates, over the period 1961-81. The decline can be traced back to 1911 when Census reported a worker population ratio of 49.9 per cent.²² Though figures

²²Table IV.6 : Work Participation Rates in UP

<u>Year</u>	<u>WPR</u>
1911	49.90
1921	52.12
1931	47.31
1951	41.50
1961	33.89
1971	30.94
1981	29.22

Source : Basic Statistics Relating to U.P. Economy 1950-51 to 1977-78, Economic & Statistics Division, State Planning Institute, UP, 1979.

from 1911 to 1981 (Table IV.6 footnote) are not strictly comparable due to definitional changes, yet, they confirm the largely accepted phenomenon of declining trend in WPR during early stages of economic development.²³ It is also to be noted that while during 1911 to 1951 WPR declined at a rate of 0.62 per cent per annum, the rate of decline has slowed down since 1961. During twenty years period 1961-81, WPR has declined at a rate of 0.23 per cent per annum. The rate has further slowed down during 1971-81. This shows the stabilising tendency in WPR and possibilities of its becoming stable and moving upwards in the future decade.

4. Growth of Labour Input : All Sectors

While WPR has declined during the three Census dates there has inevitably been an increase in the absolute number of workers as shown in Table IV.7.

Table IV.7 : Number of Workers

<u>Years</u>	<u>(in '000)</u>		
	<u>Males</u>	<u>Females</u>	<u>Persons</u>
1961	21028	3828	24856

1964-65	106.35	87.80	103.85
1965-66	108.02	84.99	104.84
1966-67	109.72	82.27	105.84
1967-68	111.44	79.64	106.84
1968-69	113.19	77.09	107.86
1969-70	114.97	74.62	108.88
1970-71	116.81	72.41	109.97
1971-72	119.01	72.48	111.64
1972-73	121.24	72.55	113.55
1973-74	123.52	72.63	115.49
1974-75	125.84	72.70	117.25
1975-76	128.21	72.77	119.03
1976-77	130.62	72.85	120.84
1977-78	133.08	72.92	122.68
1978-79	135.58	72.99	124.54
1979-80	138.13	73.06	126.43
1980-81	140.72	73.33	130.34

Source : Table IV.7.

There has been an increase of 40.72 per cent in case of male workers during 20 years period. Growth has been faster during 1970-71 to 1980-81 being 20.47 per cent compared to 16.81 per cent growth during 1960-61 to 1970-71.

In case of females, however, there has been a decline of 26.67 per cent during the whole period. There has been a decline of 27.59 per cent during the first decade and marginal increase of 1.27 per cent during the second decade. Growth rates for males and females and total working force together with growth rates of males, female and total population have been shown in Table IV.9.

Table IV.9 : Growth Rates of Working Force and Population in U.P.

Period	Male		Female		Persons	
	Working force	Population	Working force	Population	Working force	Population
1961-71	1.57	1.98	-3.18	1.64	0.95	1.82
1971-81	1.88	2.25	0.13	2.33	1.71	2.30
1981-91	1.72	2.12	-1.54	1.99	1.33	2.06

Source : For growth of working force see Table IV.8.
For growth of population see Census of India, U.P. 1961, 1971 and 1981.

Taking the working force as a whole (males and females combined) it is seen that during the study period i.e., from 1960-61 to 1980-81 growth in labour input has all along been lower than the growth of male work force in the State. This is because while females account for about 46 per cent of the total population in the State, growth of female labour input has been negative during the reference period 1960-61 to 1980-81. Thus, it has pulled down the growth of working force in the State, despite a relatively higher growth (1.72 per cent per annum) observed for male input during the period.

Comparing growth rates of working population for each sex and for combined numbers of males and females with corresponding growth rates of population, it is evident that in each case the growth of labour input has always been very slow compared to the growth of the population. While each has grown overtime, but growth of population has always exceeded the growth in the working force.

It needs to be mentioned here, that the time series of the indices of labour input given in Table IV.8 and in subsequent tables prepared for different

sectors, are all based on geometric interpolation of the bench mark estimates, and hence assume a constant geometric rate of growth, during the inter-censal period. These do not therefore measure correctly, annual changes in the estimates of the working force, that may be of substantial order, due to changes in birth and death rates and emigration and immigration of workers, from and into the State. For the lack of requisite data, for building up of such series, it has not been possible to make any adjustment on this account.

5. Sectoral Growth in Labour Input

Number of workers in the three broad sectors of the economy viz. primary, secondary and tertiary have been presented in Table IV.10. Index numbers showing sector-wise growth in labour input and growth rates during different periods have been presented in Table IV.11 and IV.12 respectively.

Table IV.10 : Number of Workers in Different Sectors

Census Year	(in '000)								
	Primary			Secondary ²⁴			Tertiary		
	Male	Fe- male	Per- sons	Male	Fe- male	Per- sons	Male	Fe- male	Per- sons

1960-61 to 1970-71	1.32	-0.90	0.16
1970-71 to 1980-81	1.32	4.67	1.95

Source : Table IV.11.

Over the period of twenty years, the secondary sector stands first in terms of growth of labour input, primary and the tertiary sectors occupy the second and the third positions respectively.

The two decades, 1960-61 to 1970-71 and 1970-71 to 1980-81, seem to differ a great deal, with respect to sectoral growth in the labour input. During 1960-61 to 1970-71 growth was fastest in the primary sector followed by tertiary and the secondary sectors; secondary sector registering a negative growth of .90 per cent per annum (Table IV.12). However, during 1970-71 to 1980-81, rate of growth was highest in the secondary sector followed by tertiary and the primary sectors.

over the two decades 1960-61 to 1980-81, rate of growth of labour input, has remained unchanged in the primary sectors.

Thus there appears to be a moderate shift in the structure of employment in the economy, especially during the second decade. Such shift, is of great importance, and needs to be studied in detail. For this purpose, percentage distribution of main workers into the three sectors has been presented in Table IV.13.

Table IV.13 : Percentage Distribution of Working Force Under Different Sectors

Sectors	1961	1971	1981
Primary	75.25	78.04	75.06
Secondary	9.69	8.05	10.70
Tertiary	15.06	13.91	14.24
Total	100.00	100.00	100.00

Source : Table IV.12.

As in all the underdeveloped agrarian economies, the primary sector in the State occupies the highest share in total employment, being more than two-thirds during the whole period of 20 years. Shares of the secondary and tertiary sectors are comparatively small; smallest being that of the secondary sector. It may further be noticed, that the share of the primary sector has increased in 1971 as compared to 1961, and declined in 1981. Census data on employment are known to suffer from severe limitations of comparability overtime, especially in case of female workers who are very sensitive to definitional changes. But it can be inferred even from the figures of male workers, that the share of primary sector in total employment has increased during 1951 to 1970-71. Reverse trends can be seen in the secondary and tertiary sectors. This structural shift in the employment, when viewed together with the shift in the structure of total output in the State, shows that while there has been a continuous decline in the share of the primary sector in total SDP, during 1960-61 to 1970-71, share of this sector in total employment has increased,²⁵

²⁵ See Chapter II of this thesis (Table II

indicating a decline in productivity per worker in this sector. This is because, agriculture, the dominant component of the primary sector, is characterised by family based subsistence farming in the State. "It can thus employ a large part of increments in the supply of labour in the guise of the family labour, independently of the average and marginal productivity considerations. When labour fails to find employment elsewhere it gets absorbed in this sector without its depressive effects on productivity becoming apparent in the short-run".²⁶ However, during the latter half of the period of our study decline in the output share of the primary sector has been accompanied by the decline in the share of employment as well. Thus, the decade 1971-81 witnessed signs of some structural diversification as evident from the decline in the share of the primary sector and increase in the employment share of the secondary and tertiary sectors.

It also appears worth mentioning that the share of the tertiary sector in total output is larger compared to

²⁶ Artreyi Majumdar, Structural Transformation and Economic Development, Birla Institute of Scientific and Economic Research Division, 1979, p.26.

the secondary sector. It shows that the secondary sector which has to play most crucial role in economic development has failed to absorb the number of workers released from the primary sector, and it is the tertiary sector, usually found to be low productivity sector²⁷ that has absorbed some of this surplus labour. A higher share of tertiary sector than that of the secondary in a backward economy like U.P. is an evidence of the incapability of the industrial sector to absorb the larger portion of the working force by creating enough job opportunities.

6. Labour Input : Qualitative Growth

The index of labour input given in Table IV.8 treats all labour as homogeneous. Individual workers may however differ from each other with respect to certain innate and acquired characteristics such as sex, ability, health and education. Not only that people in the working force at any given point of time differ from each other with respect of some of these characteristics, the distribution of many of these characteristics

²⁷ Anne Booth and R.M. Sundaram, Labour Absorption in Agriculture, Oxford University Press, 1984, p.5.

in the working force also changes with the passage of time. Most commonly noted change in this respect is the change in the sex-composition of the working force, reflected in changes in the female participation rates overtime.²⁸

Due to these inherent and acquired characteristics, contribution of different individuals to the final product also differs markedly. Hence in growth accounting studies attempts have been made to adjust the general index of labour input (as the one given in Table IV.8) for as many qualitative characteristics as are possible of quantification, particularly where noticeable changes are observed to have taken place in the qualities of working force during the period of study.²⁹ Characteristics

²⁸In developing economies "women frequently choose to pursue their traditional roles in the household. The march of modernity is likely to bring about a change in the attitudes of people and cause a difference in this. Overtime sex-composition of the working force may as a consequence change". Hicks, Mukherjee and Ghosh, The Frame Work of the Indian Economy, Oxford University Press, Delhi, 1984, p.84.

²⁹E.F. Denison, Accounting for United States Sources of Economic Growth, The Brookings Institution, Washington, 1969, p.30.

chosen for this purpose have generally been changes in the sex-composition of the working force, changes in the age-structure of the employed persons, changes in the educational and nutritional levels of the work force etc. Due to problems of data availability, quality adjustments in this study are confined to changes in the educational levels of the work force and changes in its sex-composition only.

Rationale for making adjustments for changing educational levels of the work force stems from the belief that education renders workers more productive.³⁰ While economists have long been aware of the power of education in enhancing labour productivity by incalculating knowledge and skills,³¹ the faith in education productivity link became all the more stronger since the development of the concept of 'human capital'.³² Empirical researches

³⁰M. Blaug, Education and the Employment Problem in Developing Countries, ILO, 1974 (Reprinted in 1980 by Macmillan Company of India Limited), pp.28-39.

³¹"Adam Smith for example, stressed the importance of education at various points in the wealth of Nations and the specifically included "The Acquired and Useful Abilities of all the inhabitants or members of Society" in his concept of fixed capital. See Fedrick Harbinson & Charles A. Myers, Education Manpower and Economic Growth : Strategies of Human Resource Development, Oxford & IBH Publishing Co., IIIrd Indian reprint, 1974, p.3.

³²T.w. Shultz, "Investment in Human Capital", American Economic Review, Vol.51, No.2, March 1961.

on the subject revealed that increased education of the work force has been one of the most important sources responsible for rapid economic growth of many developed countries in the western world. Denison³³ for example estimated that during the period 1929 to 1957 increased education of the work force contributed 42 per cent of the measured economic growth of per capita income in the United States. Although in case of developing countries education as a source of economic growth has been found to be relatively less important,³⁴ still it seems quite necessary and interesting to assess the role of this source in case of a backward economic State like Uttar Pradesh.

Rationale for making adjustment for changing sex-composition of the work force rests on the proposition generally found valid that a male worker is more productive than a female worker. Changes in sex-composition are taken care of simultaneously with changes in education

³³ E.F. Denison, Sources of Economic Growth in the United States and the Alternative before Us, op. cit.,

³⁴ A.P. Thirlwal, Growth and Development with Special Reference to Developing Economies, English Language Book Society, Macmillan IIIrd edition, 1985, pp.76-78.

levels by assigning separate weights to males and females with a given level of education.

7. Construction of the Quality Index

Construction of quality index of labour that measures the effect of increased educational levels and changing sex proportion of the work force, requires sex-wise break-up of the working force by broad educational levels and a set of weights to combine workers with different levels of education. Usual practice in such studies has been to use sex-wise earning differentials associated with different levels of education for the purpose of weights.

While power of education as a factor in explaining the variance of labour incomes among individuals in developing countries has been widely noted³⁵ it can in no way be denied that a part of these observed income differentials may be caused by other factors - such

³⁵ A. Berry, "Education, Income, Productivity, and Urban Poverty" in Education and Income, Timothy King (ed.), World Bank Staff Working Paper No.402, July 1980, pp.168-171.

as ability, parental education, social contacts etc. Denison³⁶ makes a deduction of two-fifth from the observed income differentials for these factors. Dholakia³⁷ makes an adjustment of one-third for these factors. However, as these factors may also be changing with the spread of education in the population, it appears more reasonable to attribute whole of the observed income differentials to education instead of making any constant adjustment for other factors effecting income, on the assumption that these factors would also be effected by the spread of education in the population. This appears to be a plausible assumption unless one has sufficient data for estimating the true income differentials associated with different educational levels, after eliminating the effect of all other variables on income. In fact "the case for making no adjustment in growth accounting (in contrast to the rate of return analysis) is much stronger than is commonly supposed, however. As education spreads through a society, each generation of young people comes from a total population of more

³⁶E.F. Denison, Sources of Economic Growth in the United States and the Alternative Before Us, op. cit, p.73.

³⁷B.H. Dholakia, Sources of Economic Growth in India, op. cit, p.121.

educated persons than in the prior generations. We know also that parental education contributes to school performance. Among the factors raising the quality of human resources over time are the contributions that come from the home environment. This means that there is no deterioration (and some times there is actually appreciation) in the quality of young people entering successively higher levels of education in latter as compared with earlier periods. To make the essentially static model adjustments for ability (even if these were not exaggerated adjustments) is then inappropriate for the measurement of the quality of the labour force.³⁸

Use of earning differentials is based on the assumption that the marginal productivities are well reflected by income differentials. This in turn pre-supposes the existence of a perfectly competitive labour market so that the equality between average-wage and the marginal product of labour is maintained. Though labour market in the State is characterised by many imperfections, the assumption may appear fairly valid provided one has

³⁸ Mary Jean Bowman, "Education and Economic Growth : An Overview" in Education and Income, op. cit, p.47.

sufficient confidence in the concept of 'labour market segmentation'.³⁹ The market can thus be conceived of as divided into different segments according to the levels of education each having its own demand and supply curves. Each market would function independently irrespective of supply and demand conditions in other segments of the market in such a manner "(i) a rise in the average rate of earnings leads to an increase in the supply and decrease in demand though with a time lag and (ii) excess demand causes average earnings to rise".⁴⁰ Use of these assumptions in the studies already made in the past, along with supporting evidence from some studies that the classic demand supply relationship holds good in the educated labour market in India although with a time lag,⁴¹ justifies our stand in using earning differentials by levels of education, as an indicator of productivity differentials.

³⁹For a review of literature on labour market segmentation see, J.P.B. Godwin, "The Definition and Analysis Local Labour Markets : Some Empirical Problems", British Journal of Industrial Relations, Vol.VIII, No.2, 1970.

⁴¹M. Blaug, P.R.G. Layard and M. Woodhall, The Causes of Graduate Unemployment in India, Allen Lane, The Penguin Press, London, 1969, p.16.

Having provided ample justification for use of observed earning differentials, we now look for the data for this purpose. As income differentials by levels of education are found to be higher in urban areas than in the rural areas of the developing countries,⁴² separate weights for both the sectors are desirable. Unfortunately however, there have been no regular surveys in the State to provide information for either sector. Hence information available from individual studies has been relied upon.

In case of the urban sector, weights have been prepared on the basis of income differentials given in the study "Women Workers in the Urban Labour Market: A study of Segregation and Discrimination in the Employment in Lucknow".⁴³ The study provides income differentials by levels of education for both the sexes. Average earnings of male and female by levels of education as given in the study are reproduced in Table IV.14.

Table IV.14 : Average Monthly Emoluments of the Establishment Workers by Educational Levels

Levels of Education	Monthly Emoluments (in Rs.)	
	Male	Female
1. Illiterate	235.00	248.68
2. Primary	261.98	309.40
3. Secondary	528.71	491.47
4. First Degree	841.83	613.84
5. Higher	1193.94	791.26
All	720.74	597.05

Source : T.S. Papola, Women Workers in an Urban Labour Market : Table V : 5, p.102, Giri Institute of Development Studies, Lucknow, 1982.

It may be noted from Table IV.14 that while for both males and females, there is a positive relationship between earnings and levels of education, income differentials by levels of education are found to favour females in the lower educational levels, and males in the higher educational ladders.⁴⁴ This highlights the

⁴⁴ T.S. Papola, Women Workers in an Urban Labour Market, op. cit, p.101.

discriminatory nature of urban labour market which differentiates against women workers in providing job opportunities.⁴⁵ Based on Table IV.14 weights for male workers with different levels of education and relative male-female weights for different educational levels are set out in tables IV.15 and IV.16 respectively.

Table IV.15 : Weights for Male Workers by Levels of Education (Treating Illiterate Male as 1)

<u>Levels of Education</u>	<u>Weights for Males</u>

Treating Male in Each Educa-
tional Category as 1

<u>Levels of Education</u>	<u>Male</u>	<u>Female</u>
Illiterate	1	1.058
Primary	1	1.181
Secondary	1	.930
Higher	1	.690

Source : Table IV.14.

Weights given in Table IV.15 show that counting work done by an illiterate male worker as 1, we count the work of a male worker not illiterate but less than or upto primary level of education as 1.115 units and so on.

Weights presented in Table IV.16 suggest that with work of an illiterate male counted as 1, we count the work of an illiterate female as 1.058 units and so on.

As no comprehensive data are available on income differentials by levels of education in the rural sector of the State, weights in case of rural male workers have been prepared from the information given in the study

"Rural Household Income and its Disposition in Uttar Pradesh"⁴⁶ Relative weights for rural females have been prepared using the information on male-female wage differentials available from the reports of Agricultural Labour Enquiry. Weights for rural male workers based on education-wise earnings data and relative male-female weights so prepared are given in Table IV.17 and IV.18.

⁴⁶Rural Household Income and Its Disposition in Uttar Pradesh, Perspective Planning Division, State Planning Institute, U.P., May 1984.

Having developed two sets of weights for combining workers with different educational levels in the urban and rural areas of the State, we now turn towards the break-up of the working force by levels of education. While Census authorities since 1961... have started providing information in this respect, the classification followed in each Census is not identical. For example while in 1971 Census workers in the educational category 'above matriculation', have been further classified as technical degree and diploma holders, graduates, and above graduates, the information available from 1961-and the 1981⁴⁷ Censuses does not strictly correspond to above, the same classification, especially for the educational category 'graduates' and 'above graduates'. In order to maintain homogeneity of classification for each Census, constrained also by the availability of weights, present study considers

⁴⁷ While for 1981 Census data on educational break-up of the working force is still awaited, the published data for educational break-up of the population also lumps together both graduates and those having above graduate educational levels.

following broad educational levels in rural and urban areas of the State.⁴⁸

Rural Sector

1. Illiterate
2. Upto primary level
3. Above primary level

Urban Sector

1. Illiterate
2. Upto primary level
3. Upto secondary level
4. Above secondary or higher educational level

While 1961 Census gave the required break-up of the working force, the data could not be used as such due to the non-comparability in the concept of 'worker' in 1961 and 1971. An exercise to make 1961 work force comparable to 1971 has been made earlier. The percentage distribution of work force by educational levels for our estimated 1961 estimates of the work force has been assumed to be the same as given in the 1961 Census. For 1971, educational decomposition of the work force given in 1971 Census has

⁴⁸ In case of rural sector category (i) includes all those who are illiterate, category (ii) includes all those not illiterate but with less than or upto primary level of education. All those having more than primary education have been included in category (iii) above primary level.

In case of urban sector categories (i) and (ii) have same meaning as in rural sector. In category (iii) all those having education more than primary but less than or upto secondary level, have been included. Those with more than secondary education have been included in the fourth category 'higher' or above secondary level.

been adopted. As data on work force by levels of education have not yet been published in case of 1981 Census, these have been estimated from the information available about the break-up of the population by broad educational levels on the assumption that, percentage distribution of the working force by levels of education would be the same as the percentage distribution of the population by levels of education. Comparable break down of the work force by educational levels at three points of time is given below for rural and urban sectors separately.

Having obtained the numbers of workers with different educational levels and the set of weights based on education earning differentials, the two sets of information have been brought together for the purpose of constructing quality index of labour. The index has been prepared following three steps : (i) in the first step female work in the two sectors rural and urban, has been converted into male work using relative weights for males and females given in Tables IV.16 and IV.18 respectively in the corresponding sectors as weight; (ii) in the second step, work performed by different educational category of male workers has been combined

separately for rural and urban sectors using relative weights for different educational categories (of male workers) from Tables IV.15 and IV.17 respectively; (iii) resulting estimates of average work performed by illiterate male workers in rural and urban sectors are added separately in the third step, using proportion of rural and urban workers in the total working force in the State (Appendix Table C₂.2) as weights. Bench mark estimates for the three Census dates - 1961, 1971 and 1981 have been interpolated to obtain the quality index of labour. Quality index along with unadjusted labour input index and labour input index adjusted for quality change (obtained by multiplying the unadjusted index and quality index) are shown in Table IV.21. Compound growth rates have been presented in Table IV.22.

Column (4) of Table IV.21 provides a measure of labour input in which labour incurred by all males and females with differing educational levels has been added together by converting into the amount of labour performed by an illiterate worker. The index does not, however, measure a host of other influences operating on the average quality of labour, such as changes in the intensity of work, associated with changes in the length of hours worked,

Table IV.21 : Adjusted and Unadjusted Indices
of Labour Input

Period	Index of labour input unadju- sted for quality change	Index of quality change as effec- ted by increased education and changing sex- composition	Index of Labour input adjusted for quality change

Table IV.22 : Compound Growth Rates per Annum
of Labour Input Adjusted for
Quality Change

Period	Labour input unadjusted for quality change	Quality of labour input as effected by increased education and changing sex-composition of the working force	Labour Input adjusted for quality change
1	2	3	4
1960-81	1.33	1.03	2.37
1960-71	.95	1.45	2.42
1970-81	1.71	.61	2.33

Source : Table IV.21.

changes in health and age-composition of the work force etc. for which no appropriate and reliable data exist in the State.

The quality adjusted index of labour input shows a growth of ^{59.93}~~56.49~~ per cent during twenty years period from 1960-61 to 1980-81 or an average compound growth of 2.37 per cent per annum. During the same period index of unadjusted labour input shows a growth of 30.34 per cent or 1.33 per cent per annum. Thus, 43.88 per

cent of measured growth of adjusted index of labour input turns out to be the contribution of education and sex-compositional changes. Looking decade-wise during 1960-61 to 1970-71 and during 1970-71 to 1980-81 these two factors viz. changes in education and sex-composition appear to have contributed ^{59.92}~~56.42~~ per cent. and 26.16 per cent of the growth in quality index of labour input respectively. It is striking to note that importance of these factors in contributing to the growth of labour input is decreasing with time being more than halved during the decade 1970-71 to 1980-81 as compared to the earlier decade.

8. Conclusion

Main conclusions of the analysis may be summarised as :

1. During 1960-61 to 1980-81 measured as the numbers in the working force, labour input in the State records

a growth of 1.33 per cent per annum. During this period its two components male and female inputs have grown at average annual compound rates of 1.72 and -1.54 per cent respectively.

2. Both male and female inputs have improved their rates of growth during 1970-71 to 1980-81 as compared to 1960-61 to 1970-71. As a consequence labour input in the economy has grown faster during the latter decade as compared to the former.

3. Due to negative rate reported by female input during 1960-61 to 1980-81, rate of labour input in the economy has been trailing behind the rate of male input.

4. During 1960-61 to 1980-81 labour input in the three sectors viz. primary, secondary and tertiary has grown at rates of 1.32, 1.85 and 1.05 per cent annually. A comparison of decade-wise performance reveals improvement in the secondary and tertiary sectors during 1970-71

to 1980-81 in comparison to 1960-61 to 1970-71. Improvement has been much faster in the secondary sector, so much so, that not only it has improved its rates during seventies as compared to sixties but has also experienced rates higher than the rates experienced by other two sectors namely primary and the tertiary.

5. During 1960-61 to 1980-81, quality of labour input due to the effect of education and changing sex-composition of the work-force has grown at a rate of 1.03 per cent per annum. Growth of quality has been slower during seventies as compared to sixties.

6. Adjustment for qualitative change raises the rate of growth of labour input from 1.33 per cent per annum to 2.37 per cent per annum during 1960-61 to 1980-81. Despite slowing down of quality change, the quality adjusted input has grown faster during seventies as compared to sixties, indicating that faster growth of labour quantity has more than offset the slowing effect of quality.

Appendix C

Owing to the need of comparable estimates for 1961 and 1971 Census, the Registrar General of Census Operations had conducted a resurvey in 1972 in rural and urban areas of 18 States (including union territories). In this survey, two independent samples were drawn from each State. In one sample 1961 Census questions were canvassed, and in the other 1971 questions were canvassed. The difference in the sample participation rates was expected to measure the net effect of conceptual difference on the participation rates in each Census*. The exercise was performed for the three main activities viz. cultivators, agricultural labourers, and other workers.

To obtain comparable estimates of workers, the Resurvey suggested an adjustment factor (to be added or subtracted) for each of the three main activities which would make 1961 and 1971 Census estimates free of conceptual differences. This factor was to be worked out as

* Samples being completely independent of each other and enquires being conducted under similar conditions and time effect due to temporal change and net effect of temporal and conceptual difference was assumed to be negligible. Sampling error for the two samples were also assumed to be of the same order.

a fixed proportion of the total population, equal to the difference between two sample participation rates.

The use of above method however led to two different rates of change in the participation rates of workers. To avoid this problem CSO has used the ratio method which ensures that the rate of change remains the same irrespective of the concept used. The method consists in multiplying the actual count of workers in 1961 Census by the ratio of actual to adjusted workers in 1971 Census. Comparable estimates of workers for different industrial categories worked out by Central Statistical Organisation are reproduced in Appendix Table C.1.

In order to obtain the comparable figures of main workers for the State, it has further been assumed here that the effect of conceptual difference in the participation rates, would be of the same order in the State, as for all-India. Thus, 1961 Census estimates of workers in the State, have been multiplied by the ratio of adjusted to actual estimates of 1961 for all-India, to yield the estimates of different categories of main workers comparable to the 1971 Census estimates of main workers. Resulting estimates together with multiplicative factors (ratio of adjusted to actual estimates of workers for all-India) for different categories of workers have been presented in Appendix Table C.1.

Table C.1 : Showing Derivation of Number of Main Workers in U.P. in 1961 Comparable to the Estimates of Main Workers Given by 1971 Census

* In case of some industrial activities ratio of adjusted to actual workers of 1961 for all-India turned out to be greater than unity. In such cases estimated worker for 1961 are larger than those reported by the 1961 Census itself. As 1961 Census definition of worker was too liberal it is doubtful that still it would have under enumerated workers for those categories. For these categories (marked by * the number of workers as reported in the 1961 Census have been accepted.

** Figures for registered and unregistered manufacturing in cols.(1) and (2) correspond to the categories non-household manufacturing and the household manufacturing in the 1961 and 1971 Censuses.

Appendix C₁

This appendix describes the method of obtaining sex-wise distribution of main workers in the estimated population of main workers in 1961. The method used is as follows :

1. As work participation rates for urban females given in 1961 Census and in 1971 and 1981 Census (main workers) are more or less comparable (Table IV.5), number of urban female workers as reported in the 1961 Census have been adopted.

2. As work participation rates for urban male workers in 1961 Census, become quite comparable with 1971 and 1981 participation rates of urban males, after excluding from 1961 Census estimates of urban male workers, workers in the age group 60 and above (Appendix Table C₁.1), the same have been excluded from total urban male workers in 1961 to obtain the comparable figures of main male workers in the urban sector.

3. Total main workers (males and females) in the rural sector have been obtained by subtracting the urban workers (males and females) from the estimated number of main workers in 1961.

4. As work participation rates for rural males in 1961 Census become quite comparable with main rural workers in 1971 and 1981, after excluding the workers in the age-group 0-14 from the Census estimates of rural workers in 1961 (Appendix Table $C_1.2$), these have been excluded to obtain the estimates of main rural male workers in 1961.

5. Having obtained the estimates of urban male, urban female and rural males in the estimated population of main workers in 1961, estimates of rural female workers have been obtained as residual, by subtracting the estimates of urban male, urban female and rural male workers from the estimates of main workers in 1961 (Appendix Table $C_1.3$).

6. Same exercise has been repeated to obtain sex-wise distribution of main workers under three sectors viz. primary and secondary; workers in the tertiary sector have been obtained as residual (Appendix Table $C_1.4$).

Table C₁.1 : Work Participation Rates
of Urban Males

Census year	WPR	
1961	51.74	(Based on number of rural male workers)

Appendix C₂

Purpose of this note is to describe briefly the main assumptions and the procedure of preparing the set of weights for the rural sector in Uttar Pradesh based on education-wise earnings data. In preparing such weights for rural male workers, reliance has been placed on the data available from the study "Rural Household Income and Its Disposition in U.P." carried out by State Planning Institute, U.P. on the basis of NCAER¹ data relating to the period June 1975 to July 1976. The study provides percentage distribution of total household income by the level of education of the chief earner² and distribution of sample households according to the education of the chief earner. Dividing percentage distribution of the household income by the percentage distribution of sample households for each educational category we have been

¹National Council of Applied Economic Research.

²The earner who contributed maximum share of the household income was treated as the chief earner though he may or may not be the head of the household. See Rural Household Income and Its Disposition in Uttar Pradesh, Perspective Planning Division, State Planning Institute, Lucknow, p.90.

able to obtain differentials in household income by levels of education of the chief earners. Main assumption behind this exercise is that differences in household income are caused only by the differences in the levels of education of the chief earners. Percentage distribution of household income and percentage distribution of sample households (both by educational level of chief earners) along with percentage income differential and derived weights are set-out in Appendix Table C_{2.1}.

Table C_{2.1} : Relative Differences in House-hold Income by Levels of Education of the Chief Earners in U.P.

Educational Level of the Chief Earner	Percentage distribution of household income	Percentage distribution of sample households	Difference in household income	Weights
Illiterate	50.37	55.81	.903	1.00
Primary	20.60	23.05	.894	.99
Above primary	29.05	21.14	1.370	1.52

Source : See the text.

Relative weights for males and females in the educational categories (1) illiterate, and (2) primary have been obtained from the male-female wage differentials.

given in the report of Agricultural Labour Enquiry³ 1974-75. Use of male-female wage differentials in agricultural operations for the purpose of relative weights is based on the fact that majority of women workers in the rural sector in the illiterate and primary educational category, are employed in agriculture.

In order to obtain relative weights for males and females in the educational category 'above primary,' male-female wage differentials in non-agricultural operations as given in ALE 1974-75 have been used.

Table C_{2.2} : Percentage of Rural and Urban Workers in Total Population

Year	Rural	Urban	Total
1961	87.99	12.01	100.00
1971	86.77	13.23	100.00
1981	82.80	17.20	100.00

Chapter V

GROWTH OF CAPITAL INPUT IN UTTAR PRADESH

Measurement of the amount of labour and capital used in the production of real income is a basic information required for an exercise on the sources of growth of an economy. Without reliable estimates of these inputs it is not possible to make any assessment of the contribution made by different sources to the growth of the economy during a given period of time.¹ The desired series of labour input required for this purpose has already been prepared in Chapter IV. The present chapter is concerned with the measurement of growth of capital input in Uttar Pradesh during twenty years period from 1960-61 to 1980-81. A number of problems are involved in the measurement of capital input and preparation of the desired series. The chapter therefore runs into three sections; Section I

¹Uma Datta Roy Choudhury, "Industrial Break-down of Capital Stock in India", Journal of Income and Wealth, Indian Association for Research in National Income and Wealth, Vol.1, No.2, April 1977, p.144.

deals with conceptual and empirical problems in the measurement of the growth of this factor, Section 2 describes the available data base and the method of preparing capital input series under the broad sectors viz. primary, secondary and tertiary of the State economy. Section 3 presents an analysis of the growth of capital input in the State and summarises main conclusions of the analysis. Appendix D gives details of methodology followed in preparing the series of capital input and Appendix E deals with measurement of growth of land input in Uttar Pradesh.

1. Concept of Capital and Problems in Its Measurement

Conceived in the sense of a factor of production capital here refers to 'real capital'. It thus includes all the structures and constructions, machinery and equipments and inventories of finished and semi-finished goods used up in the production of real-output during the period. Measurement of the growth of this real capital, however, involves many conceptual and empirical problems. Conceptual problems stem from the

very nature of the capital itself. These relate to the problem of representing by a single magnitude, the vast set of heterogeneous objects of differing vintages constituting the capital stock.² As form and composition of the assets entering into the capital stock keep on changing with time on account of technological change, it becomes all the more difficult to compare the quantity of capital existing at one point of time, with that at another point of time,³ without any reference to a suitable concept of value. The problem of measurement and comparison of capital thus lends itself into the problem of valuation of the capital stock at different points of time during the period-under consideration.

²It has however been suggested that, "the problem of combination of heterogeneous factors may be avoided through the use of the all pervasive unit of measurement - a dollar", Haney Scott, "Inferior Factors of Production", Quarterly Journal of Economics, Vol.76, 1962, p.95.

³According to Mrs. Joan Robinson, "The only case in which an exact comparison between physical stocks of capital is possible is that in which the stocks are identical item by item and the two differ only in the number of complete set of items in each", Joan Robinson, The Accumulation of Capital, English Language Book Society and Macmillan, Third edition, 1969, p.119.

Valuation of capital goods is different from the valuation of other economic goods.⁴ Ideal measurement requires that all assets in the stock be measured at their market prices. However, as capital goods already in existence and use, have a limited market, such a direct evaluation is not in fact feasible.⁵

Theoretically there are two basic approaches for valuation of the capital stock. Capital may either be valued in terms of its cost or it may be measured in reference to its future productivity.⁶ In the latter approach increases in the efficiency of capital as a result of technical advance would be embodied in the measure of capital.⁷ But, in a world of changing

⁴ "Capital can not be measured in the ordinary way as other economic goods - valuation of income goods is characteristically a market valuation, the value of goods which enter into the capital stock are characteristically imputed values", Cf. J.R. Hicks, "Measurement of Capital in Relation to the Measurement of other Economic Aggregates", The Theory of Capital, F.A. Lutz and D.C. Hague (eds.), Macmillan, London, 1961, p.19.

⁵ J.R. Hicks, *Ibid*, p.19.

⁶ Joan Robinson, "Production Function and the Theory of Capital", Capital and Growth, G.C. Harcourt and N.F. Lang (eds.), Penguin Education, 1973, pp.48, earlier published in Collected Economic Papers, Vol.2, Blackwell, 1965, pp.114-131.

⁷ C. Kennedy and A.P. Thirlwall, "Technical Progress: A Survey", Economic Journal, March 1972, pp.28-36.

technology where new capital goods are continuously entering into the capital stock and making the old obsolete, there are serious problems in estimating future productivity of a capital asset. Moreover, it has been observed that, the effect of adjusting capital stock series for embodied or endogeneous change is to raise sensitivity of the growth rate to changes in the rate of capital accumulation.⁸ In the models of disembodied technical progress, capital is usually measured with reference to its cost so that increases in the quantity of capital are reflected in the residual term, rather than in the measure of capital input.⁹ Measuring capital with reference to cost, is to measure it as an embodiment of the labour time expended in past in producing the asset, and this according to Joan Robinson¹⁰ is congenial to the production function point of view,

⁸ A.P. Thirlwall, Growth and Development : With Special Reference to Developing Economies, ELBS/Macmillan, Third edition, 1985, p.70.

⁹ C. Kennedy and A.P. Thirlwall, "Technical Progress: A Survey", op. cit., pp.28-36.

¹⁰ Joan Robinson, "Production Function and the Theory of Capital" in G.C. Harcourt and N.F. Lang (eds.), op. cit., p.48.

for it corresponds to the essential nature of capital, regarded as the factor of production.

Measurement of the capital stock in reference to its cost lies in estimating the replacement cost¹¹ of the asset, with the help of original cost data. But, the original cost of an asset will not be equal to its present replacement cost for reasons of productivity decline and price change. These being solved, capital stock for any year, selected as the base year, measures the amount of resources used in the production of various assets of the stock in that year. Valuation of the capital stock for successive years is done by adding gross annual addition and capital consumption measured at base year price, to the base year value of the stock. Thus problems of measurement and comparison of capital stock at different points of time are tackled by constructing an index of real capital stock that measures

¹¹Richard and Naney Ruggles suggests, "In a normally competitive economy, reproduction cost of capital good (in terms of economic functions) would approximate market value, so that we could ask how a given investment in the volume of capital valued at cost of production would effect annual rate of output", Cf. Richard and Nancy Fuggles, "Concept of Real Capital Stock and Services", Studies in Income and Wealth, Vol. 25, Princeton University Press, NBER, 1961, p. 398.

the value capital stock existing at those points of time at some base year prices.¹²

Besides being statistically convenient this measure is completely independent of the measurement of other factors that may contribute to output. Various merits of this measure as observed by Denison are "this method it should be emphasised is in no way dependent upon the ability to measure other factors of production whose quantity may or may not infact be measurable. Just as it is possible and interesting to compute changes in output per man hour with no knowledge of the stock of capital or other agents of production, so this method permits a parallel measurement of changes in output per unit and in particular as to whether these changes are related to the quality of other factors considered or to the quantity and quality of other productive resources with which it is combined, or to institutional factors including the growth of knowledge and scale of output."¹³

¹² Bakul. H. Dholakia, "Measurement of Capital Input and Estimation of Time Series Production Function in Indian Manufacture", The Indian Economic Journal, No.3, Vol.24, January-March 1977, pp.349-368.

¹³ E.F. Denison, "Theoretical Aspect of Quality Change, Capital Consumption and Net Capital Formation", Problems of Capital Formation : Concepts Measurement and Controlling Factors, Studies in Income and Wealth, Vol.19, Princeton, NBER, 1957, pp.223-224.

Barring the problems of measurement of capital consumption for which reliable data are largely unavailable, for all other practical reasons the method has been strongly favoured by Denison as would be obvious by the following remarks "If questions concerning proper timing of capital consumption are withheld, this method of measurement appears to be statistically feasible within reasonable limits. It is in fact the only one for which the estimates exist"¹⁴

For measuring the stock of real capital, a choice is to be made between the gross and the net measures. Due to the problems of measuring depreciation and obsolescence which introduce a potential source of error in the measurement of capital, gross stock measures have generally been favoured. The available empirical evidence also points towards a more stable relationship between gross stock of capital and output. In case of

¹⁴E.F. Denison, "Theoretical Aspects of Quality Change and Net Capital Formation", Studies in Income and Wealth, Vol.19, 1957, op. cit., p.225.

United Kingdom Tibor Barna found that efficiency of plants tended to increase rather than decrease as plant grew older, and plants were usually scrapped before their efficiency actually declined.¹⁵ There is still stronger case for use of gross stock measures in case of developing economies where capital assets are used much beyond the normally estimated economic life because of capital scarcity.¹⁶ Use of either measure however involves assumptions that may not necessarily hold true in actual life. While use of net stock measures assume that productivity of the capital assets

(ii) Many studies for the Indian manufacturing sector made earlier also find that reported figures of depreciation in sources such as Census of Manufacturing Industries (CMI) and Annual Survey of Industries (ASI) are not satisfactory as they do not measure the actual decline in the productive capacity of the plant. For instance see, S.R. Hashim and M.M. Dadi, Capital Output Relations in Indian Manufacturing (1946-64), M.S. University of Baroda, Baroda, 1973, pp.9-10; and Asit Banerjee, Capital Intensity and Productivity in the Indian Manufacturing, Macmillan, Delhi, 1975.

decline as fast as accounting procedures of depreciation reveal, use of gross stock measure rests on the extreme assumption of the constant capital services throughout the life time of the capital asset. The problem of selecting an appropriate measure of capital services has been resolved by Denison by constructing a weighted index of capital input that leans more heavily towards the gross stock measure.¹⁷ However due to the extreme scarcity of relevant data for preparing the capital stock figures, use of either measure for the purpose of analysis of economic growth becomes a matter of convenience than that of choice. Data limitations in the State do not permit use of gross stock measure. Accordingly therefore, net stock measure has been used for this study.

2. Data base and Method of Preparing Capital Input Series in the State

The problems in the measurement of capital discussed so far were of the conceptual and definitional nature. In the next step of the construction of capital input index extending over several years, one is confronted with many statistical and estimational problems,

¹⁷ E.F. Denison, Why Growth Rates Differ : Post-War Experience of Nine Western Countries, The Brookings Institution, Washington D.C., 1967, pp.140-141.

arising out of incomplete reporting of the required statistics and lack of information on certain relevant aspects. Thus, before proceeding further it would be worth while to discuss briefly the usual procedure of estimation and type of data base available in the present case for preparation of capital input series.

As mentioned earlier a satisfactory measure of capital at any point of time can be obtained by direct evaluation of all the assets at that point of time, such direct evaluation for all sectors and at different points of time is rather impracticable. Thus different methods of preparing capital stock series are used for different sectors. Most popular method in this regard is the perpetual inventory method¹⁸ where bench mark estimates of capital available for some base year are moved to other years by adding net capital formation at constant base year prices. In some cases where bench mark estimates are not available from any survey report etc. but a fairly long series of gross capital formation,

¹⁸R. Gold Smith, "A Perpetual Inventory of National Wealth", Studies in Income and Wealth, Vol. 14, NBER, New York, 1951.

base year estimates are obtained by adding the gross investment (at constant prices) each year and making allowance for depreciation on the basis of assumed average life of the asset. In cases, where adequately long series of capital expenditure is also not available, base year estimates are prepared by constructing a hypothetical series of capital expenditure at current prices.¹⁹ The series is deflated by price deflators especially prepared for the purpose, and constant price estimates of expenditure are added together after making some adjustment for depreciation, to derive the estimates of net capital stock. Net stock estimates so derived, are moved to other years on the basis of perpetual inventory method. The extreme scarcity of required

¹⁹ M. Mukherjee and N.S.R. Shastri have estimated value of private land improvements and irrigation work on the basis of a hypothetical time series of gross capital formation. This series was derived as the product of an index of per household investment in land improvement and irrigation and an index of total number of households. Index of per household investment in private irrigation and land improvement was derived by combining the index of agricultural output and rural population with equal weights. This method has also been adopted by B.H. Dholakia for estimation of value of private land and irrigation works. See,

(i) M. Mukherjee and N.S.R. Shastri, "An Estimate of the Reproducible Tangible Wealth of India, 1949-50", Review of Income and Wealth, Series VIII, R. Gold Smith and C. Saunders (eds.), Bowes & Bowes, London, 1959, pp.368-387.

(ii) B.H. Dholakia, Sources of Economic Growth in India, Goods Companion, Baroda, India, 1974, pp.184-85.

statistics and lack of even basic information in some sectors forbids the use of any single method of estimation. Thus, like all-India estimates of capital stock use of different procedures has been made to prepare the series of capital input for the State.

The basic materials required for preparing the series of real capital stock are therefore (i) the benchmark estimates of the value of net stock of capital, (ii) yearly figures of net capital formation for the required period under consideration, and (iii) price indices for various types of capital goods comprising the stock of capital. While several attempts have been made to provide the stock of capital at the all-India basis at different points of time²⁰ including a continuous

series of capital stock from 1948-49 to 1968-69²¹ no
 been
 such comprehensive estimates have/made at the regional
 basis. Only estimates available for the State are those
 of R.H. Dholakia²² (1985). Estimates relate to only two
 points of time 1960-61 and 1970-71 and provide the
 capital stock figure on sectoral basis. However Dhola-
 kia's estimates can not be regarded as completely in-
 dependently derived estimates as for certain items
 estimates have been prepared by allocating all-India
 estimates for 1960-61 prepared by B.H. Dholakia, among
 different States with the help of certain proportions.

Estimates of the value of capital for certain items
 in the capital stock for the State are, however, available
 from two nation wide surveys, carried out by Reserve Bank
 of India namely all-India Rural Debt and Investment
 Survey 1961-62, and all-India Debt and Investment Survey
 1971-72.²³ A few estimates are also available from various

rounds of National Sample Survey Reports. Still there are certain sectors like forestry, fishery, mining sectors and quarrying, construction, trade, hotels and restaurants, transport communication and other services, where no bench mark estimates of value of capital stock are available. Of course, problems are more acute in the unorganised part under these sectors. Even in the organised sector information on reliable basis is not always available for e.g. in case of organised manufacturing where information on all relevant aspects is published in the ASI reports, estimation of the real stock of capital poses serious problems.

Besides the problems caused by reported figures for capital values, which are not usable for any purposeful economic analysis without proper price deflation, and, which create problems in estimating capital stock even on the aggregative all-India basis, there are problems which are specific to the estimation of capital stock on the regional basis based on ASI data. These result, from the practice of ASI, of allocating assets of the head office to different branch offices. Problems

arise where head office and the branch offices are not situated in the same State. In such cases book value figures reported for the State in ASI, do not strictly follow the concept of capital stock within the boundaries of the State, analogical to the concept of 'income originating' as used for State income estimation.²⁴

Regarding estimates of capital formation also, the situation is not very satisfactory in the State. While estimates of both net and gross capital formation for all-India are published annually by the Central Statistical Organization no corresponding estimates for the State are available ^{from} any official source.²⁵ This is because there are special problems in estimating gross fixed capital formation at the State level²⁶ such as

²⁴ R.H. Dholakia and P.M. Patel, "On Estimating, Net Fixed Capital Formation at Constant Prices in Registered Manufacturing Sector at State Level", The Journal of Income and Wealth, Vol.4, No.1, January 1980, pp.26-31.

²⁵ However capital formation by the State Government is published annually in the Budget Documents of the State Government.

²⁶ While at the national level capital formation estimates are prepared using the three approaches namely the commodity flow approach saving investment approach and the expenditure approach, the first two are not very useful for preparing the regional estimates. Non-availability of basic data on export, imports of capital goods across the State boundaries, is the main reason.

those caused by non-availability of any basic data on exports and imports of capital goods across the State boundaries as well as the net inflow from and outside the State. Only approach suitable for estimating capital formation at the State level is the expenditure approach.²⁷ Adoption of this approach also, poses problems in procuring State-wise expenditure figures in some cases. In case of multi-State projects which extend over many States, such as the construction work undertaken by Railway and Communication Departments etc, only the overall expenditure figures are available. As expenditure on constructing railway track etc. depends not only on the length of the track but also on climatic and topographical conditions of the region, State-wise allocation of total expenditure figures on the basis of a single variable like kilometerage of track may not be very accurate.

Not only there are problems in procuring data needed for estimation of fixed capital formation at the State-

²⁷ For problems of estimating gross fixed capital formation at the State level the reader is referred to D.N. Chaturvedi, "Problems of Estimating Gross Fixed Capital Formation at the State Level in the Journal of Income and Wealth, Vol.4, No.1, January 1980, pp.23-25.

level such estimation raises some conceptual issues also, for example, where the investment made by a State falls within the geographical boundary of the State but the benefits of the investment are shared by many other States. While adjustments are warranted for dividing the total investment between output sharing States, such adjustments leave distortions in capital-output ratios and limit their applicability for deriving capital stock estimates, especially when capital is to be measured from functional point of view.²⁸

Despite the problems in the measurement of capital input at the State level, attempts have been made both individually and institutionally to estimate capital formation in the State. Estimates of both gross and net capital formation have been prepared. Gross capital formation estimates for the period 1960-61 to 1972-73 have been prepared by R.N. Lal.²⁹ Gross capital formation by

²⁸ M.M. Dadi and S.R. Hashim, "Long-Term Trends in Capital Output Ratios in Indian Economy and Related Measurement Problems", Journal of Income and Wealth, Vol.4, No.2, July 1980, p.72.

²⁹ R.N. Lal, Capital Formation and Its Financing in India, Allied Publishers and Private Ltd., 1977.

major asset groups with no sectoral break up has been provided. Another set of capital formation estimates are those prepared by Perspective Planning Division, State Planning Institute, Uttar Pradesh.³⁰ Estimates of net capital formation have been prepared for the Fourth and the Fifth Plan Period i.e. from 1969-70 to 1978-79.³¹ Sectoral classification has also been given. However, neither of the two series are adequately long to cover the entire period of study and nor of them provides constant price estimates needed for preparing real capital stock series. Price deflators needed for

³⁰ Perspective Planning Division, State Planning Institute Lucknow, Uttar Pradesh.

- i. Investment in Uttar Pradesh during Fourth Plan
- ii. Capital Formation in Uttar Pradesh during Fifth Plan
- iii. Capital Formation in the Economy of Uttar Pradesh : A Study of Development Head-wise Estimates, 1969-70 to 1978-79.

The (iii) will hereafter be referred as SPI estimates.

³¹ Uttar Pradesh Development and Systems Corporation (UPDESCO) has also undertaken some exercise at preparing capital formation estimates during the Sixth Plan period. However, the estimates have not been published as yet.

converting current price estimates into constant prices are also not available for the State and one has to depend on all-India price deflators available for this purpose.³²

Methodology of preparing capital stock series for the State adopted for the present study has been highly constrained by the nature and availability of data discussed in the preceeding paragraphs. As the study follows broad sectoral classification viz. primary, secondary and tertiary, separate real stock series (at 1970-71 prices) for all the three sectors are required. Aggregation of the three series would provide the capital input series for the State. A systematic procedure of preparing real stock series for the three sectors mentioned above requires bench mark estimates of the net capital stock and continuous time series of net capital formation or of gross capital formation with related rates of depreciation each year. However, as

³²While some price indices are now prepared for the State also like the index number of prices of machinery and transport equipment, these are available from 1970-71 and onwards only. As the study period in this study extends from 1960-61 to 1980-81; use of all-India indices has been made.

mentioned earlier, comprehensive attempts for preparing independently the bench mark estimates of value of the capital stock on aggregative and sectoral basis are still awaited in the State. Only estimates available are those of R.H. Dholakia.³³ While Dholakia provides capital stock estimates for broad sectors also, the estimates could not be used for preparing capital input series for the State. Though it should have been possible to extend the capital stock estimates prepared by Dholakia for the year 1970-71 to other years with the help of net capital formation series prepared by SPI,* this required first, converting the 1970-71 estimates of capital stock^{***} at 1970-71 prices for all sectors. Again, net capital formation estimates by State Planning Institute need to be converted at 1970-71 prices. As neither Dholakia nor SPI study provides any idea about the composition of the assets in the capital stock, like structures, machinery and equipments and inventories no appropriate composite price index taking account of variations in the prices of different capital goods in the stock is easily conceivable. Still there would have

³³ R.H. Dholakia, op. cit., 1985.

* See State Planning Institute, Lucknow.

* * Dholakia's estimates are at 1960-61 price.

remained the problem of estimating net capital formation for the period 1960-61 to 1968-69, at 1970-71 prices.

Use of Lal's³⁴ series of gross capital formation for extending the bench mark estimates prepared by Dholakia also does not serve the purpose, for capital formation according to broad sectors has not been attempted in the study. Nor is his series sufficiently long to cover the study period adopted for the present study.

With all these limitations in view, neither Dholakia's bench mark estimates, nor the gross and net capital formation series prepared by SPI and R.N. Lal have been used. Series of real capital stock for different sectors have been prepared following different methods for different sectors. Methodology adopted for sectoral estimates is discussed below.

³⁴R.N. Lal, op. cit., 1977.

Primary Sector

Estimation of capital stock series for different sub-sectors in the primary sector has been undertaken separately.

An attempt to measure state-wise growth in capital stock in the agricultural sector during 1961-77 has been made by A.K. Das Gupta.³⁵ However his measure seems to have left out two important items in the stock viz. stocks in the form of private^{irrigation} and public irrigation works. His study also seems to have omitted the urban farm houses. Besides all this, his study does not provide money value of the stock for the bench mark years. As such, his estimates are not of much help to us, and we have undertaken an independent exercise to measure the growth of capital stock in agriculture by preparing separate estimates for various assets in the stock.

³⁵ A.K. Das Gupta, Growth and Composition of Agricultural Capital Stock in Indian State, 1961-77, Hindustan Publishing Corporation (India), 1984.

Capital stock in agriculture consists of following major asset groups (i) farm houses, (ii) machinery and equipments, (iii) livestock, (iv) private irrigation works, (v) public irrigation works, and (vi) inventories. Six capital input series in respect of these asset groups have been prepared using the information available from different sources as given below.

(i) Farm Houses : In case of farm houses bench mark estimates of house property available from all-India Rural Debt and Investment Survey 1961-62 and all-India Debt and Investment Survey 1971-72 have been used. These refer to the market value of rural house property in the State as on 30th June 1961 and 30th June 1971 respectively. Following the conventions set by Uma Datta and Vinod Prakash,³⁶ Mukherjee and Shastri³⁷ and RBI,³⁸ one third of this value after making a 5 per cent discount

³⁶ Uma Datta and Vinod Prakash, op. cit.

³⁷ M. Mukherjee and N.S.R. Shastri in Review of Income and Wealth, op. cit.

³⁸ Reserve Bank of India, "Estimates of Tangible Wealth in India, RBI Bulletin, Vol. XVIII, No. 1, January 1963.

for the value of land has been taken to constitute the value of farm houses in the rural sector. Estimates for the urban sector have been obtained by observing the proportions of rural and urban workers in the total agricultural workers of the State. Estimates for rural and urban sectors in 1960-61 and 1970-71 have been interpolated to obtain the estimates for the intervening years. Index numbers of cost of construction in rural and urban areas have been used for converting current price estimates at constant prices. The values of farm houses after 1970-71 have been obtained by moving rural and urban values in 1970-71 by the index number of residential dwellings in rural and urban sectors respectively, prepared with the help of information on Census houses given in 1971 and 1981 Census. Changes in the quality of Farm houses are assumed to be reflected in the residual term rather than in the capital input itself.

(ii) Machinery and Equipments : In case of machinery and equipments also, basic information has been obtained from the Survey Reports. Bench Mark estimates of the

value of agricultural machinery and equipments available from AIRDIS (1961-62) and AIRDIS (1971-72), have been interpolated to obtain the estimates for intervening years. Estimates for the urban sector have been obtained as in case of farm houses. Index number of machinery and transport equipment has been used to convert the current price estimates into constant 1970-71 prices. Since no bench mark estimate of the value of agricultural machinery for 1980-81 could be available, estimate for 1970-71 has been moved to other years upto 1980-81, with the help of physical index of agriculture machinery and transport equipment or 'agricultural machinery equivalent' especially developed for this purpose.

(iii) Livestock : Capital stock in the form of livestock has been estimated using the information on number of animals given in different Livestock Censuses in the State. Bench mark estimates have been interpolated to obtain estimates of the number of animals of different categories for the inter-censal years. Prices of different categories of animals in 1970-71, as obtained

from State Planning Institute, U.P., have been used as weights to evaluate the value of total livestock for each year during 1960-61 to 1980-81.

(iv) Private Irrigation Works : In order to evaluate value of the capital stock in the form of private irrigation works in the State, information given in the special survey on capital formation³⁹ conducted by Economic and Statistics Division, State Planning Institute for the year 1969-70 has been used. Value of urban private irrigation works in 1969-70 has been obtained in the same way as value of urban farm houses. Value figures for 1969-70 have been brought at 1970-71 prices by the index of cost of construction in the rural sector. The rural and urban estimates have been combined and moved to other years on the basis of index of net area irrigated by private irrigation works in the State.

(v) Public Irrigation Works : Series of capital stock in the form of public irrigation works in the State,

³⁹ Capital Formation in the Rural Sector of Uttar Pradesh 1969-70, (in Hindi), Economic and Statistics Division, State Planning Institute, Uttar Pradesh.

has been obtained by accumulating capital expenditure figures each year, with the help of a fairly long series of capital accumulation available from the State Irrigation Department. Assuming an average life of 50 years, depreciation at the rate of 2 per cent has been charged for each year. Accumulated expenditure for 1938-39 after making due allowance for depreciation is assumed to constitute the value of capital stock in 1938-39.⁴⁰ Value of stock in 1938-39 has been deflated by the index of cost of construction ^{to bring it at 1970-71 prices.} Net investments in public irrigation works each year during 1938-39 to 1959-60 (at constant 1970-71 prices) have been added to the 1938-39

⁴⁰ Same procedure has been adopted by Tara Shukla for evaluating stock of capital during 1920-21 to 1960-61. She argues "The decade from 1938-39 to 1948-49 witnessed almost a four-fold increase in the general price level, whereas the preceding decade of 1930 to 1939 showed very little change in prices in spite of the depression years..... Also in the two decades before 1930, the general price level rose for the first half and fell in the second half, leaving the final value of the index unchanged. This too gives the ground for assuming that the book value of the assets in 1938-39 would not be very much different from their current market value". Cf. Tara Shukla, Capital Formation in Indian Agriculture, Vora & Company Pvt. Ltd., Bombay, 1965, p.133.

value, to obtain the value of stock in 1960-61. Stock value figures for 1960-61 are moved to other years with the help of net investment series in public irrigation works at constant 1970-71 prices.

(vi) Inventories : Adopting RBI practice⁴¹ inventory holding of crops in the agricultural sector is assumed to constitute 10 per cent of the value added.

Time series of capital stock in agriculture according to the asset groups discussed above, have been presented in the Appendix Table D.4.

In case of other subsectors viz. mining, forestry and fisheries, no bench mark estimates of the value of capital stock in the State could be available. Lack of capital expenditure figures in these sub-sectors especially in the unorganised part, on a reliable basis, and for sufficiently long period of time, makes it difficult to follow any systematic procedure, for estimating the stock of capital under these sub-sectors.

⁴¹ Reserve Bank of India, "Estimates of Saving and Investment in the Indian Economy : 1950-51 to 1962-63", RBI Bulletin, March 1965.

Hence capital stock series for these two sub-sectors have been prepared using all-India capital output ratios (Appendix Table D.6).

Capital input series for above sub sectors have been added up for obtaining capital input series in the primary sector, presented in Table V.1.

Table V.1 : Capital Input in the Primary Sector (at 1970-71 Prices)

Period	(in crore Rs.)			
	Agriculture	Forestry	Fishing	Total capital input in the primary sector
1960-61	2646.83	10.83	3.21	2660.87
1961-62	2726.12	12.27	3.49	2741.88
1962-63	2755.92	13.90	3.79	2773.61

1976-77	4338.90	43.64	12.21	4394.75
1977-78	4481.67	44.69	13.27	4539.63
1978-79	4660.04	45.76	14.42	4720.22
1979-80	4659.55	46.86	15.67	4722.08
1980-81	4830.11	47.98	16.89	4894.98

Secondary Sector

As in the primary sector, separate capital stock series for all the sub-sectors under the secondary sector have been prepared. Except for the mining and construction sectors, where no bench mark estimate of the value of capital stock could be available, for all other sub-sectors, capital stock series has been prepared with the help of State data.

Registered Manufacturing, Electricity, Gas and Water Supply

The two sub-sectors, registered manufacturing and electricity, gas and water supply are organised sectors. Estimation of capital input series in these sectors has been undertaken on the basis of information provided in ASI⁴¹ reports. Even in these sectors which are completely organised and are supposed to be well placed from

⁴¹For estimating the stock of capital in registered manufacturing sector, information available from ASI Census sector and sample sector reports, has been pooled. The combined sample and Census report for the State are available from 1967 only.

the point of view of reliability and regularity of the statistics, many difficulties discussed widely in growth measuring studies in the manufacturing sector⁴² were encountered.

Major problem with ASI data is that the figures of capital stock as reported in ASI are not well in conformity with the concept of capital measurement desired for the study. ASI, for example, reports depreciated book values of the capital assets. The book value of capital in any particular year, represents accumulation of annual additions to the stock of capital in the past, valued at their historical prices, net of depreciation charges. In order to obtain some consistent value of capital in any particular year, all the past additions to the capital

⁴²(i) B.H. Dholakia, "Measurement of Capital Input and Estimation of Time Series Production Function in Indian Manufacture", op. cit., p.333.

(ii) Asit Banerjee, Capital Intensity and Productivity in the Indian Industry", Macmillan India Ltd., 1975.

(iii) S.R. Hashim and M.M. Dadi, Capital Output Relations in Indian Manufacturing (1946-64), MS University of Baroda, 1973.

(iv) B.N. Goldar, Productivity Growth in Indian Industry, Allied Publishers Pvt. Ltd., 1986.

stock must be converted to that year's prices. This adjustment in prices requires age structure of capital stock each year.⁴³ As information on this aspect is not available from ASI, estimation of fixed capital stock series becomes rather difficult.

Fixed capital stock series for the registered manufacturing sector in the State has been prepared, using the perpetual inventory method which consists of, first, deriving the value of fixed capital stock at some base year prices, and then adding to it net investment in fixed capital each year at base year prices.

In order to obtain value of the fixed capital stock in 1960-61 at 1960-61 prices, it has been observed that book value of fixed capital reported in ASI for 1960-61 is not very large, being Rs.78.29 crores only. Keeping in mind the industrial backwardness

⁴³S.R. Hashim and M.M. Dadi, Capital Output Relations in Indian Manufacturing (1946-64), op. cit., p.19.

of the State,⁴⁴ it can generally be presumed that much of this capital must have been formed during the First and Second Plan periods. This being true, reported figure in 1960-61 would not represent capital stock older than 10 years. From the Census of Manufacturing Industries,⁴⁵ book value of fixed capital in 1955 has been obtained. As no marked variations in the price index were noticed during 1949-50 to 1954-55, it can be safely concluded, that book values in 1954-55 would not be very much different from their current

⁴⁴The industrial backwardness of the State is evident from the fact large and small scale industries including the unregistered manufacturing units contributed only 10 per cent of the State income during the year 1970-71, while for the national economy the corresponding share was 15.9 per cent in 1969-70. Of the 10 per cent contribution of the manufacturing sector in 1970-71, 61 per cent was due to the unregistered sector, the percentage for the country being 39 in 1969-70. See Five Year Plan : Draft Annual Plan 1978-79, Planning Department, U.P., 1977, p.66.

⁴⁵Census of Indian Manufactures, Government of India, Directorate of Industrial Statistics, Delhi Annual Publication, 1955.

values. The book value figure for 1954-55 has been converted at 1960-61 prices.⁴⁶ Annual additions to the capital stock during 1954-55 to 1960-61, (at 1960-61 prices) are added to this stock value to yield estimate of fixed capital in 1960-61.

Having obtained the bench mark estimate of the fixed capital stock in 1960-61, the net investment series (obtained by subtracting from the current year's figure, the ^{previous} base year figure) deflated properly to bring it at 1960-61 prices, has been used to obtain the stock of fixed capital for the subsequent years. "Obviously, application of price correction to such a series is likely to have more meaning because each yearly addition to the capital stock is likely to show greater homogeneity as compared to the total book value in terms of quality, vintage and prices."⁴⁷

⁴⁶ The price index of manufacturing goods used for this purpose has been the one used by Hashim and Dadi. See, S.R. Hashim and M.M. Dadi, Capital Output Relations in Indian Manufacturing (1946-64), op. cit., p.24.

⁴⁷ A. Banerjee, Capital Intensity and Productivity in the Indian Manufacturing, op. cit., p.21.

Series of fixed capital stock at 1960-61 prices has been converted at 1970-71 prices by shifting the base of the index number of machinery and transport equipment to 1970-71 = 100 (Appendix Table D.5).

Working capital values obtained from ASI have been deflated by the index of whole-sale prices to convert them at 1970-71 prices. working capital and fixed capital series are combined together to obtain the time series of stock of capital input in the registered manufacturing sector of the State.⁴⁸

Similar procedure has been used to obtain the capital input series in the sector 'power, gas and water supply'.

Unregistered Manufacturing

Owing to the scattered nature of economic activity in this sector, both in rural and urban areas, coupled with pre-dominance of enterprises run on the household

⁴⁸ Since working capital in ASI included cash in hand also it has not been possible to exclude it from the capital input series.

basis, regular statistics needed for preparing capital stock series are not available. Capital input series in this sector, has been prepared with the help of rather scanty information available for this purpose.

From 29th round of the National Sample Survey,⁴⁹ we obtain the value of owned assets per household in the unregistered manufacturing sector of the State in 1974-75. Total value of owned assets and gross value added in this sector have been deflated by the index, number of machinery and transport equipment and general index of industrial whole-sale prices respectively. These have been adjusted for depreciation at a rate of 10 per cent per year, and have been used to work out capital output ratio for this sector in 1974-75. This ratio has been moved to other years on the basis of index of average capital output ratios for the registered manufacturing sector in the State. The resulting capital output ratios have been used to work out series of capital input in the unregistered manufacturing sector of the State (Appendix Table D.7).

⁴⁹ Report No. 280/3, Tables with Notes on Survey of Self-employed Households in Non-agricultural Enterprises-Detailed Results, 29th Round July 1974-June 1975, National Sample Survey Organization, Ministry of Planning, Govt. of India, 1978.

The above exercise is based on the assumption that capital output ratios in the unregistered manufacturing sector would move in the same direction and almost at the same rate as the capital output ratios in the registered manufacturing sector of the State.

Construction

As mentioned earlier value of capital stock in this sector could not be available. Hence all-India capital output ratios (see Appendix Table D.6) have been used to work out the capital input series in this sector.

Capital input series for the secondary sector has been obtained by aggregating the capital input series in all the sub-sectors falling under it. Estimates are presented in Table V.2.

Table V.2 : Capital Input in the
Secondary Sector at 1970-71 prices.

(Rs. In crore)						
Period	Min- ing & Qua- rry- ing	Un- regis- tered manu- factu- ring	Regis- tered manu- factu- ring	Power, gas & water supply	Constru- ction	Total

Source : As per methodology discussed in the text.

Tertiary Sector

As no bench mark estimates of the value of capital stock for different sub-sectors in the tertiary sector like transport, storage and communication, trade, hotels and restaurants etc. could be available, all India capital output ratios (Appendix Table D.6) for these sub-sectors have been used to obtain capital stock estimate for this sector in the State.

In preparing capital stock of this sector we have however, excluded stock in the sub-sectors - 'public administration' and 'real estate and ownership of dwellings'. Capital stock in the form of public buildings, roads, bridges etc. falling under the head 'public administration' has been omitted to maintain consistency between the State income series and the capital stock series. This is because, although the State income series includes income from non-residential structures and constructions, machinery and equipments etc. of the government departmental enterprises, it does not include income accruing to general government capital. The sector 'real estate and ownership of dwellings' has been excluded, because, not only do the estimation of capital

stock in house property is difficult due to problems of varying vintages, cost changes and market valuation etc, but also, output of this sector includes some notional elements as well. And any functional relationship between the estimated stock of capital and the notional output becomes rather meaningless, when productivity and efficiency aspects are important.⁵⁰ Total capital stock in the tertiary sector excluding public administration and real estate and ownership of dwellings has been presented in Table V.3.

Series of capital input prepared so far in Table V.1, V.2 and V.3 have been aggregated to obtain the broad sectoral estimates of capital input. Resulting series together with total capital input series in the State (obtained by adding the three sectoral estimates) has been set out in Table V.4.

⁵⁰ "our proposition is that for purpose of production function of the economy and such other exercises which have implications for efficiency and productivity, house property should not be counted as part of the capital stock. It introduces big element of notional estimates. For such purposes house property should be considered at par with other consumer durables", M.M. Dadi & S.R. Hashim, "Long Term Trends in Capital Output Ratios in the Indian Economy and Related Measurement Problems" in the Journal of Income and Wealth, Vol.4, No.2, July 1980, p.72.

Table V.3 : Capital Input in the Tertiary Sector (at 1970-71 prices)

Source : Tables V.1, V.2 and V.3.

The time series of capital input prepared here takes no account of the intensity of capital use. If same machine is used more intensively in one period than in the other or machine with improved quality but same cost are put to use, they are not expected to effect the capital input measure. Such changes are assumed to be reflected in the measure of total factor ^{productivity} ~~input~~ or the residual. No adjustment for capacity utilization has been made for the lack of data.

3. Trends in the Growth of Capital Input

3.1 As mentioned earlier this section attempts to analyse the measured growth of capital input and trends in its rate of growth during the study period. For this purpose indices of real capital input in the State as well as sectoral indices have been presented in Table V.5.

Column 5 of Table V.5 reveals that total capital input in the State has grown more than two-fold during twenty years period i.e., from 1960-61 to 1980-81. However, it has grown more fast during the first half of the period i.e., from 1960-61 to 1970-71 showing a

Table V.5 : Indices of Real Capital Input
in Broad Sectors

Period	Primary sector	Secondary sector	Tertiary sector	All sectors

1977-78	170.61	517.19	186.23	213.77
1978-79	177.39	558.38	193.03	224.26
1979-80	177.46	580.72	200.10	229.52
1980-81	183.90	608.57	207.64	238.70

Source : Table V.4.

growth of 62.14 per cent compared to 47.22 per cent growth during the later half of the period.

Looking sector-wise, it is found that highest growth in capital input has occurred in the secondary sector. It increased more than six times during the two decades. Noticeable fact however, is that while during the first decade capital input in this sector increased by 243.97 per cent, during the latter decade it increased by 176.93 per cent only.

Tertiary and the primary sectors rank second and third respectively in terms of growth of capital input. Here also, capital input (in both the sectors) grew more in former decade, compared to the latter decade.

Growth rates of capital input in the State along with sectoral growth rates have been presented in Table V.6.

Table V.6 : Growth Rates of Capital Input in 'UP'

Periods	(Compound growth rates in per cent per annum)			
	Primary sector	Secondary sector	Tertiary sector	All Sectors
1960-61 to 1970-71	3.17	13.15	3.80	4.95
1970-71 to 1980-81	3.01	5.87	3.64	3.94
1960-61 to 1980-81	3.09	9.45	3.72	4.45

Source : Table V.5.

Column 4 of Table V.6 shows that total capital input in the State economy during the twenty years period i.e., from 1960-61 to 1980-81 grew at a compound rate of 4.45 per cent per annum. It has, however, grown more rapidly during the first decade compared to the latter decade. Growth rate during 1970-71 to 1980-81 comes around 3.94 per cent which is 1.01 percentage points lower compared than to the growth rate experienced during the period 1960-61 to 1970-71. Similar trends are observed in sectoral growth rates also.

While total capital input in the State is the aggregation of sectoral capital inputs, the power of any sectoral growth rate to alter the over-all growth rate of capital input in the economy depends on that particular sectoral growth rate and share of that sector in total capital input.⁵⁰ Sectoral growth rates have already been presented in Table V.6, sectoral shares in total capital input have been presented in Table V.7.

⁵⁰ Overall growth rate in the economy may be looked upon as the weighted sum of the sectoral growth rates, weights being shares of the sectors in total capital input.

Table V.7 : Percentage Share of Different Sectors in Total Capital Input in the State

period	Primary sector	Secondary sector	Tertiary sector	All sectors
1960-61 to 1970-71	44.20	6.97	48.83	100.00
1970-71 to 1980-81	38.92	25.14	35.94	100.00
1960-61 to 1980-81	41.08	17.70	41.22	100.00

Source : Table V.5.

Table V.7 shows over the study period of twenty years. Secondary sector accounts for the smallest share in total capital input in the State. Shares of the primary and tertiary sectors turned out to be almost equal and much larger than that of the secondary sector. Looking period-wise, it is seen that during first decade i.e., 1960-61 to 1970-71 tertiary sector had the maximum share followed by primary sector, the two together accounting for about 93 per cent of the total capital. Large shares of the tertiary and the primary sector in total capital input are the result of government's deliberate efforts to develop the infra-structural base and high priority accorded to agriculture

during the three plans and annual plans. Relative decline in the shares of primary and tertiary sectors in total capital input in the latter decade, compared to the previous one, indicates the shift in emphasis from agriculture and tertiary sector to the secondary sector which has yet to play its crucial role in economic development of the State.

Due to the heavy weight acquired by the primary and tertiary sectors in the total capital input, any marginal change in the rate of growth capital input in these sectors would effect the overall growth rate of capital input more significantly, compared to the changes in growth rates of capital input in the secondary sector, which has, but a smaller weight in the total capital input. It is for this reason, that despite a 13.5 per cent growth per annum in the secondary sector during 1960-61 to 1970-71, overall growth rate of capital input in the State kept as low as 4.95 per cent per annum. For the same reason, a marginal decline of 0.16 percentage points in the growth rate of the primary sector and 0.16 percentage points decline in the tertiary sector along with a 7.28 per cent decline in the secondary sector, lowered the overall growth rate of capital input by 1.01 per centage points only.

Because of data limitations and weaknesses in the methodology used for preparing capital input series, the estimates derived (Table V.4) are rough and need to be used with care. It is expected however that year to year changes in capital input as also the total change during the period would not be much different from that revealed by the series prepared by us (Table V.6) and this only serves as a point of content since when technology is changing continuously, a precise measure of capital increase or decrease is not possible.⁵¹

3.2 Conclusions

Main conclusions emerging from the analysis are summarised as :

1. During 1960-61 to 1980-81 real capital input in the State economy has grown at an annual compound rate of 4.45 per cent per annum. Its growth has been slower during 1970-71 to 1980-81 in comparison to 1960-61 to 1970-71.

⁵¹ "Not-with-standing any refinement that may still be possible, with only a vague notion of more or less capital. We must be glad if our measure allows us to distinguish to our common sense satisfaction between two different quantities when the difference is large enough", Cf. Fedrick Lutz, "The Essentials of Capital Theory" in the Theory of Capital, F.A. Lutz and D.C. Hague (eds.), Macmillan, London, 1961, p.16.

2. During the two decades 1960-61 to 1980-81, real capital input in the three broad sectors primary, secondary and tertiary has grown at annual compound rates of 3.09, 9.45 and 3.72 per cent respectively. In all the three sectors rates are lower during seventies as compared to sixties.
3. Despite the fact that over the two decades secondary sector has revealed the fastest rate of growth of capital input in the State economy, percentage share of this sector in total capital input is the smallest; reflecting the low level of industrial activity in the State. It is encouraging, however, that percentage share of this sector has improved during seventies as compared to sixties.

Appendix D

This appendix describes the method of estimating real capital stock series in the agricultural sector of the State. Different items of the stock mentioned in the text earlier have been estimated as follows:

Farm Houses

In order to evaluate value of farm houses in the State at 1970-71 prices information available from AIRDIS 1961-62 and AIDIS 1971-72 has been utilised. These two survey reports provide the market value of house property with rural households as on 30th June 1961 and 1971 respectively. Following the procedure adopted by earlier studies on tangible wealth¹ one-third of the value of

¹(i) Uma Datta and Vinod Prakash, "An Estimate of Reproducible Tangible Wealth in India, 1949-50," op. cit.

(ii) M. Mukherjee and N.S.R. Shastri, "An Estimate of Reproducible Tangible Wealth in India", Review of Income and Wealth, op. cit.

(iii) Reserve Bank of India, "Estimates of Tangible Wealth in India", RBI Bulletin, Vol.XXVI, No.10, October 1972.

house property with cultivators and agricultural labour households² after making a 5 per cent discount for the value of land is assumed to constitute value of stock in the form of farm houses in rural sector for 1961 and 1971 respectively. Estimates for intervening years have been obtained after by Interpolating the bench mark estimates of 1961 and 1971. These have been deflated by the index number of cost of rural construction to obtain the constant price estimates.

As both AIRDIS and AIDIS provide information in case of rural household sector only, bench mark estimates of urban value of house property in 1960-61 and 1970-71 have been obtained, assuming that urban value would from same percentage of rural value, as urban agricultural workers to rural agricultural workers. A deduction of 10 per cent has been made to account for the value of land in the urban sector. Estimates for intervening years have been obtained by interpolation. These have

² While AIDIS gives estimates of house property for both cultivators and agricultural labour households separately, AIRDIS provides this information for rural cultivating households only. Estimates of house property with agricultural labour households in 1961 has been estimated, assuming that lowest category in terms of value of asset holding among the non-cultivator households consists of agricultural labour households.

been deflated by the index number of cost of construction in the urban sector, to obtain constant price estimates. Estimates for rural and urban sectors are added year-wise, to obtain value of capital in the form of farm houses for the period 1960-61 to 1970-71. Value of farm houses in 1970-71, in rural and urban sectors, have been moved forward with the help of indices of number of residential dwellings³ in the two sectors, to obtain estimates for the years 1960-61 to 1980-81.

Agricultural Machinery and Equipments

Two bench mark estimates of the value of agricultural machinery and equipments for 1961 and 1971 have been obtained from AIRDIS and AIDIS respectively. AIRDIS 1961-62, gives Rs.165.82 crores as market value of agricultural machinery and equipments with the rural cultivating households on 30th June 1961. Value of agricultural machinery and equipments with agricultural

³Prepared by using information given in 1971 and 1981 Census on number of dwellings in rural and urban sectors of the State.

labour households is estimated as Rs.0.89 crores for the same period.⁴ Value of agricultural machinery and equipments with urban households is assumed to constitute same percentage of rural machinery and equipments as the ratio of urban agricultural workers to rural agricultural workers, thus, yielding a figure of Rs.1.66 crores. Rural and urban estimates add to Rs.168.15 crore.

Using the same procedure, AIDIS gives Rs.466.74 crores as market value of agricultural machinery and equipment on 30th June 1971. Bench mark estimates for 1961 and 1971 so obtained, have been interpolated to obtain estimates for the intervening years. Resulting estimates being at current prices have been deflated by the index number of machinery and transport equipments (given in Appendix Table D.1) to obtain constant price estimates at 1970-71 prices.

No studies could be available to estimate value of agricultural machinery and equipments for the years 1970-71 to 1980-81. Only information available in respect of

⁴ Method followed for estimating value of agricultural machinery and equipments with agricultural labour households is the same as used in case of farm houses.

agricultural machinery, relates to numbers of different items given by quinquennial Live-Stock Censuses in the State. However, due to their heterogeneous nature, these items could not be added as such, to obtain the total number of agricultural machinery and equipments for the Census dates. To solve this problem, an agricultural machinery and equipment equivalent has been prepared, by using prices of different items of machinery as weights. Prices for development of these weights have been obtained from the price list of Agro Industrial Corporation Limited, Tal Katora, Lucknow and relate to the year 1984-85. Prices of the items not included in the list of Agro Industrial Corporation Limited have been ascertained from the engineering section of the State Directorate of Agriculture, Lucknow. These prices have been used to combine the different items of agricultural machinery yielding thereby, what may be called Agricultural Machinery Equivalent for the bench mark years 1971-72 and 1977-78. Estimates for the intercensal years have been obtained by interpolation. Estimates of the equivalent for 1970-71 and for the years 1978-79, 1979-80 and 1980-81 have been obtained assuming same percentage growth per annum as between 1972 and 1978. Value of agricultural machinery and equipments

Livestock

Estimates of number of animals under different categories were available from different livestock Censuses in the State. Bench mark estimates available for 1961, 1966, 1972 and 1978 Censuses have been interpolated to find the number of animals for inter-Censal years. Number of animals under different categories each year from 1978 to 1981 have been obtained by assuming same percentage growth as obtained from the livestock Censuses during 1972 and 1978. Prices as available from Economics and Statistics Division of the State Planning Institute, U.P. for 1970-71 have been used to evaluate value of total livestock for each year. These prices are reproduced below in Appendix Table D.3.

Table D.3 :

<u>Animals under different categories</u>	<u>Prices in 1970-71</u>
1. Cattle male over 3 years	250.07
2. Milched cow over 3 years	94.10
3. Cows not calved even once	47.63
4. Cattle others	11.10
5. Cattle young stock	69.14
6. Buffaloe male over 3 years	420.76
7. Milched buffaloe over 3 years	410.10
8. Buffaloe not calved even once	209.24
9. Buffaloe others	69.58
10. Pigs	58.95
11. Sheep	39.69
12. Goats	47.93
13. Fowls	4.71
14. Ducks	5.88
15. Others poultry	3.76

Private Irrigation Works

In case of private irrigation works bench mark estimate of capital stock for the rural sector has been obtained from a special survey undertaken in the State, by Economic and Statistics Division of the State Planning Institute in 1969-70, published under the title "Capital Formation in Rural Sector of Uttar Pradesh,⁵ a special survey". The report gives Rs.290.89 crores as the value of the private irrigation works (includes private wells only) in the State as on 30th June 1970. Value of private irrigation works in the urban sector is estimated, in the same manner as in case of farm houses and agricultural equipments, described earlier. The two estimates have been deflated by the index of cost of construction in rural and urban sectors respectively, to convert them at 1970-71 prices. Net stock of capital in the form of private irrigation works comes to Rs.306.08 crores in 1969-70. Estimates of net capital stock for other years have been obtained by carrying backward and forward the bench mark estimate for 1969-70 with the help of index of net area irrigated by private wells in the State.

⁵Capital Formation in the Rural Sector of Uttar Pradesh (in Hindi), op. cit.

Public Irrigation

In order to obtain series of capital stock in public irrigation, use of capital outlay figures available from State Irrigation Department has been made. The first step has been to estimate net capital stock for the bench mark year 1960-61. For this purpose average life of public irrigation works is assumed to be 50 years. On the basis of this assumption it can easily be concluded that capital stock in 1960-61 would not constitute capital older than 1911. Net investment in public irrigation during 1910-11 to 1938-39 (after making a 2 per cent allowance for depreciation) have been aggregated to obtain net capital stock in 1938-39. This value is expected to be pretty close to its current value, as the index of general price level and so presumably the cost of construction index did not reveal any marked change during 1910-11 to 1938-39*. For the latter period upto 1960-61, net investment each year has been deflated by the index number of cost of

⁶See 1) Tara Shukla, Capital Formation in Indian Agriculture, Vora & Company, Bombay, 1965, pp.131-138.

2) M. Mukherjee and N.S.R. Shastri, Review of Income and Wealth, 1959, op. cit., p.386.

construction in the urban sector to convert them at constant 1960-61 prices. Resulting accumulated figure when added to the net capital stock in 1938-39 provides an estimate of net capital stock in the form of public irrigation works in the year 1960-61.

Since we require series of real capital stock at 1970-71 prices for the period 1960-61 to 1980-81, the 1960-61 estimate of net capital stock has been converted at 1970-71 prices by shifting the base of the index of cost of construction at 1970-71 = 100.

Estimates of capital stock for other years during the reference period have been obtained using the identity.

$$K_t = K_{t-1} + I_t$$

where,

K_t = net capital stock in year t .

K_{t-1} = net capital stock in year $t-1$.

I_t = net investment in year t .

All valued at constant prices.

Estimates of various items in the capital stock for the agricultural sector have been presented in Appendix Table D.4.

Appendix EGrowth of Land Input in U.P.

Land as a factor of production occupies a distinct place among the primary factors needed for production of goods and services. Land is different from capital, not because it is a 'free gift of nature' as Marshall¹ believed, but because it is relatively immobile and inelastic in supply, and has a some-what negative rate of depreciation and obsolescence². Land derives importance from its innate qualities such as fertility, possession of minerals etc. and also due to its locational advantage.³

¹Marshall, Principles of Economics : An Introductory, Vol.VIII, edition, Macmilland & Company Ltd., St. Martin's Street, London, 1938, p.138.

²"It (land) can be kept permanently in good order by a relatively small expenditure of resources on running repairs (hedging and ditching) and that it can be put to a wide variety of uses, so that it is not much subject to wear and tear and the obsolescence due to change in demand for its services that limits the useful life of a machinery. At the same time in a settled country, it is very expensive if not physically impossible to increase the supply of land (as for instance by draining fence or irrigating deserts). Consequently the supply of land varies much less than supply of most kinds of capital goods in response to changes in income that can be got by owning it Land is often subject to a kind of negative obsolescence as when the development of a new crop turns formerly useless jungles into rich productive resources". J. Robinson, The Accumulation of Capital, Macmillan, IIIrd edition, 1969, pp.12-13.

³E.F. Denison, Sources of Economic Growth in the United States and the Alternatives Before Us, Supplementary Paper No.13, Committee for Economic Development, New York, 1962, p.87.

Importance of land as a factor of production is all the more greater in the production system of a predominantly agricultural economies with high rate of population growth where increased demand for food and other necessities, make it even more scarce.

The concept of land to be used for measuring sources of growth has been some what controversial. The controversy exists as to whether the total land available to the economy or the land in actual use should be used for measuring input of land in the production. E.F. Denison⁴ uses the concept of total available land. As total land available in the economy for use, is not likely to change under usual circumstances, his index of land input does not diverge from 100. However, in many other

⁴(i) E.F. Denison, Sources of Economic Growth in the U.S., op. cit., p.90.

(ii) E.F. Denison, Accounting for the United States Sources of Economic Growth, 1929-1969, The Brookings Institution, Washington, p.57.

studies⁵ on sources of economic growth, the concept of land input used is that of land actually in use.

While it is true that total land available to the economy remains almost fixed, its quantity in actual use does change with time due to technical advancement and investment of more capital. Denison⁶ while recognising that increase in land area in actual use by bringing into use, land that was previously unused or which had little economic value is likely to make a positive contribution to the growth of output, justifies his stand for using 'land available' concept, on the ground that share of land in net output in the United States being a very small percentage of net output, use of either concept is not likely to effect his results. However, in

⁶E.F. Denison, op. cit., pp.90-91.

case of India and so also for Uttar Pradesh which are predominantly agrarian economies relative share of land in net output is quite large. For Uttar Pradesh share of land during 1960-61 to 1980-81 works out to be around 60 per cent of net domestic product. Empirical studies also confirm that increase in land area has made a significant contribution to the growth of agricultural output in the State.⁷ and at the national level.⁸ Land area in agriculture in the State is increasing though with a declining rate. It, therefore, appears more appropriate to use the concept of land in actual use rather than available land for use, as a measure of land input for the present study.

⁷ By decomposing growth rates of crop output into components of area yield and cropping pattern V.N. Misra's study reveals that during 1950-53 to 1956-59 area accounted almost entire growth in crop output. Its contribution in subsequent periods i.e., 1956-59 to 1962-65, 1962-65 to 1968-71 and 1968-71 to 1974-77 worked out as 12, 17 and 3 per cent respectively showing somewhat a declining trend. See, V.N. Misra, "Anatomy of Agricultural Growth" in T.S. Papola et.al. (eds.), Studies on Development of Uttar Pradesh, GIDS, Lucknow, 1979, pp.1-57.

⁸ Growth Rates in Indian Agriculture, Directorate of Economics and Statistics, Ministry of Food and Agriculture, Govt. of India, 1967.

Index of land input in this study measures only the growth in net sown area and fallow land.⁹ While use of this measure does not raise any problems for the agricultural sector (or the primary sector as defined in our study) it certainly fails to take into account growth in land area in other sectors of the economy. In this sense it is a partial measure of land input. This is not of course, to ~~deny~~^{suggest} that increase in land area makes no contribution to the growth of output at all in sectors other than agriculture but that it is only in agriculture that land derives value even without much investment made on it, and earnings of land can be separated from the earnings of capital. In all other sectors of the economy it is rather difficult, if not impossible, to identify and separate out the earnings of land from that of capital, as much of the appreciation in land values is due to heavy investment made on it, in the form of buildings and structures.

⁹Tara Shukla in her study Capital Formation in Indian Agriculture uses the concept of net sown area and fallow land for the purpose of the study. B.H. Dholakia also uses the same concept for measuring land input in agriculture. See, Tara Shukla, Capital Formation in Indian Agriculture, Vora & Co., Bombay, 1965. B.H. Dholakia, Sources of Economic Growth in India, op. cit., pp. 191-192.

In the absence of any information about Govt. land in the form of roads, parks, bridges etc. Dholakia assumes that half of the land under the category 'non-agricultural' land constitutes Govt. land. See, B.H. Dholakia, Sources of Economic Growth in India, op. cit., pp. 191-192.

Thus, increase in the quantity of land in all other sub-sectors is assumed to be included in the measure of capital in those sectors. Further, land used for non-agricultural purposes has increased only by 80 per cent during the study period 1960-61 to 1980-81.¹⁰ A substantial part of this increase must have been due to increase in land area for residential houses and for government land under roads, parks and bridges etc. which are not part of this study. Remaining increase in land area under commercial purposes, is not likely to be so much as to effect the measure of land input in the economy, because of its small weight in total land area in use, in the economy.¹¹ Hence our index of land input prepared by measuring the increase in net sown area and fallow land, measures the growth of land input in the economy. Statistics of land utilisation issued by Board of Revenue and Directorate of Agricultural Statistics, Deptt. of Agriculture, Uttar Pradesh available for all

¹⁰ "Classification of Land Utilisation Statistics U.P." in Agricultural Statistics in U.P., Directorate of Agriculture, Govt. of U.P. (different issues).

¹¹ During the year 1960-61 only 6.48 per cent of the reported land area in the State was under non-agricultural uses. This percentage has not changed significantly over the twenty years period 1960-61 to 1980-81. In the year 1980-81 only 7.54 per cent of the reported land area was under non-agricultural purposes. See, Classification of land Utilisation Statistics in U.P. in Agricultural Statistics in U.P., op. cit.

years from 1960-61 to 1980-81 have been used. The index prepared has been shown in Table E.1.

Table E.1 : Index of Land Input in U.P.

Year	Net sown area and current fallow land (in '000 hectares)	Land input (index)
1960-61	17362	100.00
1961-62	17444	100.47
1962-63	17434	100.41

Chapter VIMEASURING THE CONTRIBUTION OF SOURCES OF GROWTH
OF REAL INCOME IN UTTAR PRADESH

This chapter is aimed at measuring the contribution of various sources to the growth of real income in the State economy during the period of two decades from 1960-61 to 1980-81. The sources of growth have been classified under two major heads - (i) conventionally measured inputs, and (ii) technical change. The conventionally measured inputs are the trinity of the primary factors — land, labour and capital. The term technological change refers to all those sources which lead to changes in technology and thereby help to produce (i) quantitatively more, and (ii) qualitatively superior output per unit of given resources.¹ While the qualitative aspect is in no way less important than the quantitative aspect,² problems involved in measurement of the former compell us to confine the analysis to the

¹N. Rosenberg, Inside the Black Box : Technology and Economics, Cambridge University Press, 1982, p.1.

²Ibid, p.2.

quantitative aspect only. Quantitative importance of various sources of growth has been assessed using growth accounting technique in the neo-classical framework. The chapter has been presented into two sections; Section 1 : deals with theoretical base of measurement and Section 2 : deals with measurement and analysis of sources of growth.

1. Theoretical Basis of Measuring Contribution of Conventionally Measured Inputs and Total Factor Productivity*

The main premise behind the growth accounting exercise is that growth in output is the result of growth in factor quantities and growth in factor productivities. Thus by measuring the growth rate of total factor quantity and total factor productivity, the growth rate of real income can be totally accounted. The term "total factor quantity" refers to the increase in the primary factors:

* There are various names given to the term "total factor productivity" such as technical change, measure of efficiency, measure of our ignorance, output per unit of resource input and residual etc.

land, labour and capital. The term "total factor productivity" refers to the combined efficiency of the measured inputs or growth in output per unit of total factor input. This part of growth stems from a number of sources such as increased education of the work force, improvements in managerial skill, changes in resource-shifts, economies of scale etc. These sources are numerous and invisible and it is difficult to identify and measure them precisely by any conventional yardstick. Hence their combined contribution to the growth is measured as a residual which remains from the growth rate of income after subtracting the contributions of conventionally measured inputs. The growth accounting exercise is, therefore, concerned with separating out growth due to quantity increase from that due to productivity increase.

Total factor productivity measures can be deduced either from the distributive theory or from the explicitly

assumed production functions.³ In both cases production function serves as the base.

In the early post-War research on productivity growth total factor productivity measures used were the standard sort of output per unit of resource input measures. The well distinguished studies in the field by Schmookler⁴, Abramovitz⁵, and Kendrick⁶ for the

⁵M. Abramovitz, "Resource and Output Trends in the United States since 1970", American Economic Review, Vol.46, No.2, May 1956, pp.5-23.

⁶J.W. Kendrick, Productivity Trends in the United States 1948-69, Princeton University Press, Princeton, 1961.

United States were based on this simple index.⁷ The fact that different components of total factor input grow at different rates over time was taken care of by weighting the input indexes with the help of factor prices. Neither the assumption of profit maximisation nor that of competitive equilibrium and full employment were postulated. Solow however pointed out that "it might seem at first glance that calculations of output per unit of resource input provide a relatively assumption free way of measuring productivity changes. Actually I think the implicit load of assumptions is quite heavy".⁸ Using the explicit assumption of an aggregate production function he was able to show that the standard measure of output per unit of resource input had in the background assumptions of (i) neutral technical change (ii) perfect competition and strictly linear aggregate production function.⁹

⁷Kendrick's index for the year t may be written as

$$A_t = \frac{Y_t}{w_0 L_t + r_0 K_t}$$

where, Y , L and K denote the values of real output, labour and capital and w_0 and r_0 denote the factor rewards of labour and capital in the base year.

⁸R.M. Solow, "Technical Change and Aggregate Production Function", The Review of Economics and Statistics, Vol. 39, August 1957, pp. 312-320.

⁹Ibid.

Production function is a micro concept. A production function is a relationship between inputs, output and technology. Given the assumption of perfect competition in product and factor markets, equality of factor price and marginal products and profit maximising behaviour of the firm, increase in output resulting from a small increase in only one input keeping others constant will be the same as the share of that input in total factor return. Thus, for any growth in inputs, output would grow proportionately along the production function. Residual, if left, would measure the shift in production function or technical change.¹⁰

A production function portrays all the efficient production techniques existing at a given time. A shift in the function can also occur due to application of previously known but unused techniques. Such a shift in the strict sense should not be confused with technical change. In practice "it is not always possible

¹⁰R.R. Nelson, "Research on Productivity Growth and Productivity Differences : Dead Ends and New Departures", Journal of Economic Literature, Vol.XIX, September 1981, pp.1029-1064.

to operate with such purity to distinguish movements in efficiency due to movements towards known production boundaries, from the expansion of the boundaries themselves",¹¹ unless the assumption of neutral technical change is made.¹²

Though essentially a micro concept the characteristics obtained for micro production function have been postulated for macro functions also. To conceive of such a function at the economy level gives rise to

¹¹C. Kennedy and A.P. Thirlwal, "Technical Progress: A Survey", Economic Journal, Vol.82, No.325, March 1972, pp.11-12.

¹²Technical change is said to be neutral if the shift in the production function is such that the balance between capital and labour in the current production i.e. factor shares remain undisturbed. Three types of neutrality have been discussed in literature (i) Harrod neutrality, (ii) Solow neutrality, (iii) Hicks neutrality. Technical change is Harrod neutral when the shift in the function is such that capital output ratio remains the same. It is Solow neutral if production function shifts in such a manner that labour output ratio remains constant. Technical change is said to be neutral in Hicksian sense when for a given capital labour ratio marginal rate of substitution between capital and labour does not change with change in technology. See :

(i) Paul Stoneman, The Economic Analysis of Technological Change, Oxford University Press, 1963, pp.4-7.

(ii) Arnold Heertje, Economics and Technological Change, Weidenfield and Nicolson, London, 1979, pp.161-72.

serious problems of aggregation. Aggregation of micro-economic functions into corresponding macro-economic function even in the most simple case where all enterprises produce homogenous end products with the help of only one capital and same labour, is possible only if the micro functions can be decomposed into two parts, separately for the use of labour and capital.¹³ Problems are naturally more acute when different economic units produce heterogeneous products with the help of heterogeneous inputs. Led by these problems some economists cast doubts on the existence of such an aggregate function. Walter, for example, remarks "After surveying the problem of aggregation, one may easily doubt whether there is much point in employing such a concept as aggregate production function. The variety of competitive and technological conditions we find in modern economies suggest that we can not approximate the basic requirement of sensible aggregation except perhaps over firms in the same industry or for the narrow sections of the economy".¹³ Some economists¹⁴ however believe

that these problems are not so acute as to suggest... abandoning the function altogether. Thus, despite the criticism levelled against the aggregate concept, the function in implicit and explicit forms has been used extensively for exploring sources of growth in different economies.¹⁵

Assumption of aggregate production function provides the basic frame work for assessing the contributions of various sources to the growth of output. Various forms of production function have been proposed and used for empirical study. For the purpose of present study we start by assuming the set of most convenient conditions of (i) neutral technical change, (ii) perfectly competitive equilibrium conditions, (iii) equality of factor price and marginal product, and (iv) constant returns to scale. These conditions imply that we implicitly assume a function of the form :

$$Q = A(t) f(K, L) \quad \dots\dots (1)$$

where, $f(K, L)$ is homogeneous of degree 1 and

$$\begin{array}{ll} Q & = \text{Output} \\ K & = \text{Capital (inclusive of land)} \\ L & = \text{Labour} \end{array}$$

All measured in physical terms.

The multiplicative term $A(t)$ measures the cumulated effect of shifts over-time.

Differentiating (1) with respect to (t) and dividing by

Q we get :

$$\frac{\dot{Q}}{Q} = \frac{\dot{A}}{A} + \frac{1}{f} \left[K \cdot \frac{\delta f}{\delta K} \cdot \frac{\dot{K}}{K} + L \cdot \frac{\delta f}{\delta L} \cdot \frac{\dot{L}}{L} \right] \dots\dots\dots (2)$$

where dots denote time derivatives.

$$\text{Defining } WK = \frac{\delta t}{\delta K} \cdot \frac{K}{f}$$

$$\text{and } WL = \frac{\delta t}{\delta L} \cdot \frac{L}{f}$$

and substituting in eq (2), we get

$$\frac{Q^{\circ}}{Q} = \frac{A^{\circ}}{A} + WK \cdot \frac{K^{\circ}}{K} + WL \cdot \frac{L^{\circ}}{L}$$

i.e. growth rate of output is equal to the growth rate of technological change plus the weighted sum of the growth rate of factor inputs; weights being the shares of inputs in total factor return.

As mentioned earlier, Kendricks' index of measuring total factor productivity, used factor prices to weight the input indices, "with no elaborate justification of this as means of tracking movements along a production function".¹⁶ Factor prices measure the contribution of a factor to the growth of output only at the margin. But in growth accounting studies dealing with long periods when percentage changes in inputs and output are substantial, marginal productivity of any factor is not independent of the rates of growth of other factors. Nelson has rightly observed that "the fact that yearly increases in labour, capital and gross national product are typically

¹⁶R.R. Nelson, op. cit, p.1058.

quite small should not obscure the fact that even over a period as short as a decade, the percentage changes are substantial. If there is any curvature to the isoquant, the marginal productivity of any factor towards the end of the decade, is influenced by the relative growth of different factors, over the decade. This is a well known deficiency with analysis of growth based on factor price weighted index".¹⁷ Use of factor shares in place of elasticity of substitution rather than factor prices to estimate the marginal products is definitely superior because "even though the marginal productivity of a factor falls as it increases relative to other factors along a production function, its share need not".¹⁸

In this implicitly assumed form of production function contribution of any measured input to the growth rate of output is obtained as the product of the growth rate of input and its share in total output. The contribution of technological change is obtained by subtracting the total contribution of measured inputs from the growth rate of output. Being obtained as residual total

¹⁷R.R. Nelson, op. cit, p.1053.

¹⁸Ibid.

factor productivity or technical change includes the set of all intangible sources like education, health improvements, resource utilization, resource shifts economies of scale etc. It also includes the errors in the measurement of inputs and output.

The assumption of constant returns to scale does not actually mean that economy during the period under consideration was operating under constant returns. It only implies that effects of increasing or decreasing returns would be manifested in the measure of Total Factor Productivity¹⁹ or technical change; biasing it upward in case of increasing returns and downwards in case of decreasing returns.

The assumption of perfectly competitive equilibrium and equality of factor prices with their marginal products, are hard to justify in case of the economy under study here. Due to prevalence of large scale disguised unemployment, marginal product of labour is likely to diverge from its price. However, given the assumption of rationality on the part of economic units and the

¹⁹ Hereafter referred as TFP only.

fact that many empirical studies dealing with these assumptions have yielded satisfactory results, provide a reasonable basis for analysis.

2. Measurement and Analysis of Sources of Growth

In the exercise of measurement of the sources of growth for the State economy, the first step is to separate the contribution of total factor input and total factor productivity from the growth rate of real output (SDP) by constructing an index of total factor input with the help of input indices prepared in earlier chapters. Absolute and relative contributions of 'total factor input' and its main constituents to the growth rate of SDP would then be measured.

This part of the chapter has accordingly been divided into four sub-sectors. Section 2.1 measures the contribution of 'total factor input' and its components to the growth of real SDP assuming technical change to be purely disembodied; Section 2.2 presents sectoral analysis of the sources of growth; Section 2.3 attempts measurement and analysis of the sources of growth with labour embodied technical change and Section 2.4 summarises main conclusions of the analysis.

2.1 Contribution of Total Factor Input : Total factor input index or more accurately multi-factor input index²⁰ which embodies all the measured inputs growing at different rates overtime is crucial for any exercise on sources of economic growth.

The index of total factor input²¹ for the economy of U.P. during 1960-61 to 1980-81 has been prepared as a weighted sum of the indices of three conventional inputs — labour, capital and land prepared earlier in chapters IV and V. For combining these inputs the set of weights used are the relative income shares of the three factors in SDP estimated in chapter III. Due to the established superiority of the changing weight index over the fixed weight index,²² the sets of weight used have been changed after every five years. The choice of quinquennium for using the same set of weights is "to see that the marginal product weights assigned to

²⁰ The index of total factor input usually fails to account for all the inputs used in production. Hence some people prefer to call it multi-factor input index instead of total factor input index, see, K.L. Krishna, op. cit, pp.701-706.

²¹ Hereafter referred as TFI only.

²² E.F. Denison, Sources of Economic Growth in United States, op. cit., p.140.

different factors of production are changed often enough to catch the persistent changes but not so often as to allow cyclical fluctuations in income shares to cause the results to be sensitive to the particular year in which the quantity of a factor increases".²³ The index of TFI along with indices of its individual components has been shown in Table VI.1. Corresponding growth rates along with the growth rates of real SDP have been shown in Table VI.2.

Source : See Table VI.1.

2.1.1 Changes in Total Factor Input : Table VI.1 shows that during the twenty years period, 1960-61 to 1980-81, TFI has grown by nearly 47 per cent i.e. at an average compound rate of 1.94 per cent per annum. From the growth rates given in Table VI.2 it is also apparent that TFI has tended to increase with the passage of time; growth rate in each successive period being higher than in the preceding one. During the first decade i.e. 1960-61 to 1970-71, total factor input grew at an average compound

rate of 1.64 per cent per annum, while during the second decade it grew at an average compound rate of 2.25 per cent per annum. Different sub-divisions of the time period 1960-61 to 1980-81 also reveal an acceleration of the growth rate of TFI over-time.

As TFI is the weighted sum of the factor inputs, labour, capital and land, reasons for increasing rate of growth of TFI are to be found in the growth rates of factor inputs and changes in the relative shares of factor inputs in the value added.

A close look at Table VI.2 reveals a marked similarity in the growth pattern of total factor input and labour input; growth rates of both increasing during successive time periods. Growth rates of other two inputs namely capital and land reveal opposite trends. As labour input also acquired the largest share of value added during the reference period 1960-61 to 1980-81 and in each of the sub-periods, 1960-61 to 1970-71; and 1970-71 to 1980-81, it follows that labour input has been the dominant component of TFI during the period under consideration. While growth rates of other two inputs, namely capital and land have declined during 1970-71 to

1980-81, compared to the previous decade, because of their low weights in terms of income shares, these inputs have not been successful in generating any appreciable impact on the growth of TFI.

Despite the upward tendency revealed by TFI it is interesting to note that, of the two major components of TFI namely labour and capital, the rise in the growth rate of labour has been associated with a fall in the growth rate of capital, reflecting the substitution of labour for capital in the growth process.

2.1.2 Sources of Economic Growth : Factor Inputs and Technical Change : Contribution of each component of TFI viz, labour, capital and land is estimated initially as the product of the growth rate of factor input and its relative share in income during the period under consideration. For example, contribution of labour to the growth rate of SDP during 1960-61 to 1980-81 has been estimated as the product of its growth rate (1.33) and its average share in State income during the period (63.19) . Wherever sum of the separate contributions of labour, capital and land, fell short of the measured contribution of TFI to growth rate of SDP, the resulting

difference or the interaction factor, has been allocated among the individual components of TFI, in proportion to the share of each in value added.

Contribution of technological change or TFP to the growth rate of State income has been worked out by subtracting the rate of growth of TFI from the rate of growth of real SDP. Estimated contributions of various sources in absolute and relative terms have been shown in Tables VI.3 and VI.4 respectively.

Table VI.3 : Absolute Contribution of Various Sources to Growth Rate of SDP in U.P.

Source : Table VI.3.

Of the two major sources of growth TFI and TFP accounting for the growth rate of real income, former has been more important than the latter except during 1974-75 to 1980-81. Relative contributions of TFI and TFP during 1960-61 to 1980-81, worked out to 71.59 per cent and 28.41 per cent respectively. Decadal analysis shows that relative importance of TFI has increased over time while that of total factor productivity has decreased. Not only relative contribution of TFP has declined during the

second decade i.e. 1970-71 to 1980-81 compared to the earlier decade i.e. 1960-61 to 1970-71 but also its absolute contribution in percentage points.

As could generally be expected, labour and capital have been two major sources of growth of output during 1960-61 to 1980-81. However, over the period contribution of labour is seen to be higher compared to capital. This may be to some extent a reflection of the weakness of the assumption of equality of marginal product of factor and its price because of structural disequilibrium in the labour market, so that wages may be in some excess to the marginal product of labour.

Decadal analysis, however shows, that relative importance of labour and capital as sources of growth had not been uniform during the period 1960-61 to 1980-81. During the first decade capital played more important role, its contribution being 9.45 percentage points higher than that of labour. During the latter decade i.e. 1970-71 to 1980-81 importance of capital as a growth inducing source declined relative to labour. These variations can easily be explained in terms of variations in growth rates of these two inputs given in Table VI.2.

The analysis also brings to light the smallness of the contribution made by land input to the growth rate of real GDP in the State. Relative importance of this input is seen to have declined with time. The green revolution which emphasised the use of high yielding varieties, cropping intensity and use of chemical fertilizers, appears to have been the major factor accounting for this decline.

Decadal analysis suggests that diminishing returns have been seen in the State economy. A different picture is, however, revealed if we divide the reference period into three parts viz., 1960-61 to 1967-68; 1967-68 to 1974-75 and 1974-75 to 1980-81. The break in points 1967-68 and 1974-75 have been chosen since the year 1967-68 represents a year from which onward the new agricultural technology started yielding results. The second break in point of time 1974-75 has been chosen as it was the year from which a stable and faster growth of real income was noticed in the economy.

During the period 1960-61 to 1967-68, total factor productivity growth turns out to be negative, showing that although, large investments were made in irrigation, basic industries and infrastructure development, during

the earlier Five Year Plans, they could not yield returns. Among the factor inputs, capital is observed to have contributed the largest. A 59.70 per cent contribution of capital with a negative 21.64 per cent contribution of technology shows that quality of labour was too poor to absorb the new technology embodied in capital goods. Available evidence for many developed countries reveals that they were successful in achieving high rate of economic growth because they were able to master the technology embodied in new capital goods.²⁴

During the period 1967-68 to 1974-75 absolute contribution of capital increased in comparison to 1960-61 to 1967-68. However in relative terms, contributions of both capital and land declined, while that of labour declined only marginally. TFP growth though positive was still very slow, being 0.20 percentage points only showing the slow absorption of technology.

²⁴On the basis of information for ten countries, compiled from P.R. Bramhananda, Productivity in the Indian Economy : Rising Inputs for Falling Outputs, (Himalaya Publishing Co., 1982); S. Rajra concludes that Japan, Germany, Brazil, Argentina and many other countries could accelerate their rate of growth because they could master technology and achieved higher rate of technological progress, S. Rajra, Capital and Technological Progress in the Indian Economy, 1950-51 - 1980-81, Radiant Publisher's, New Delhi, 1985, pp.18-19.

During the period 1974-75 to 1980-81, TFI becomes a less important source of growth compared to TFP. More than fifty per cent of growth in real income during this period stems from growth of technology. Labour remains the largest contributory source among the factor inputs, though, in comparison to the earlier period contribution of each factor input declined. During this period rate of growth of real income is slightly more than the rate of growth of capital input, reflecting thereby that the economy has started absorbing the technical change accumulated in the capital goods. During this period contribution of TFP is more than three times that of capital input.²⁵

²⁵On the basis of Denison's study, Why Growth Rates Differ : Post War Experience of Nine Western Countries, The Brookings Institution, Washington, D.C., 1967. S. Hajra has observed that in majority of the developed countries studied by Denison, contribution of technological progress was two to three times that of the contribution of capital. S. Hajra, op. cit, pp.13-14.

2.2 Sectoral Analysis of the Sources of Growth

The analysis carried so far was in aggregative terms. Existence of non-homogeneous production functions, different forms of economic organisation and... different natural conditions under which production is being carried out require that analysis of sources of growth be carried on sectoral basis.²⁶ In fact such analysis is imperative for understanding the process of growth of the economy and hence aggregate productivity change, admitting of course the fact that sectoral analysis is subject to all those criticism which are levelled against the Partial Equilibrium Analysis of Marshall.²⁷ This part of the chapter is therefore concerned with sectoral analysis of the sources of growth. Three broad sectors distinguished for this purpose are the primary, secondary and tertiary. Analysis of sources of growth for each of them has been presented separately in sub-sections 2.2.1, 2.2.2 and 2.2.3.

²⁶ Narrottam Shah, "Exploring Sources of Income Growth in India : A Suggested Conceptual Frame-work", The Journal of Income and Wealth, Vol.2, No.1, Oct. 1977, pp.72-75.

During the reference period i.e. 1960-61 to 1980-81 TFI has grown at an average compound rate of 1.35 per cent per annum (Table VI.5). Growth rate of TFI has, however, declined during the latter decade i.e. 1970-71 to 1980-81 compared to the earlier one (Table VI.6). Breaking the period of two decades into three sub-periods with break in points at 1967-68 and 1974-75, it becomes obvious that growth rate of TFI has been fluctuating. It declined from 1.33 per cent per annum during 1960-61 to 1967-68, to 1.25 per cent per annum during 1967-68 to 1974-75 and increased again in 1974-75 to 1980-81, exceeding even the rate experienced during 1960-61 to 1967-68. Changes in the rates of growth of labour, capital and land and in their relative shares, seem to be the factors responsible for this fluctuation.

Growth rate of TFI in this sector lies in close vicinity to the growth rate of labour input, reflecting the labour absorbing nature of the sector.

Analysis of the rate of growth of real income shows that over the reference period 1960-61 to 1980-81, TFI contributed more than three-fourth of the growth of output. A little less than quarter of the

growth came from TFP. As expected, labour turned out to be the largest contributor both in absolute and in relative terms. Capital was the second important source of growth after labour and contributed slightly more than one-fourths of the growth of output. Land's contribution seemed to be the smallest being 6.78 per cent only.

Decadal experiences show that there has been a significant decline in the absolute and relative contributions of TFI and significant increase in the absolute and relative contributions of TFP during 1970-71 to 1980-81 as compared to the earlier decade i.e. 1960-61 to 1970-71. Relative importance of individual components of TFI to the growth rate of output remained largely the same during the two decades with labour contributing the largest part, followed by capital and land. But, relative contribution of each of these sources has declined during the latter decade compared to the former. It can be seen from Table VI.6 that except capital, absolute contributions of other two inputs i.e. labour and land are lower in the latter decade in comparison to the former.

The decade 1970-71 to 1980-81, therefore shows signs of some improvements in the performance of the primary sector. However, the pattern of growth is brought out more vividly by studying behaviour of output, inputs, and total factor productivity during three sub-periods, 1960-61 to 1967-68; 1967-68 to 1974-75 and 1974-75 to 1980-81.

During 1960-61 to 1967-68 largest and smallest contribution came from labour and land respectively. Growth rate of TFI exceeded the growth rate of output and TFP made a negative contribution (Table VI.6 and VI.7). During 1967-68 to 1974-75 absolute contributions of labour and capital increased relative to the period 1960-61 to 1967-68, while that of land declined. TFP made positive but a small contribution to the growth of output.

A perceptible change, however, seems to have occurred during 1974-75 to 1980-81. Absolute contributions of all the inputs (except labour) increased during this period in comparison to the earlier period i.e. 1967-68 to 1974-75. During this period TFP made a larger contribution than that the contribution of TFI.

It may be pertinent to note here that total factor productivity in the primary sector is determined largely by the magnitude and direction of total factor productivity in the agricultural sector. It is also widely known that productivity in the agricultural sector besides stemming from such sources as increased application of new and improved seeds, use of chemical fertilisers, changes in cropping pattern and cropping intensity is greatly conditioned by natural factors like droughts, floods, crop damages due to pests etc. And it is only when the production structure develops enough strength to over-power the random disturbances caused by the natural phenomena that a steady rate of increase in output is possible.²⁸ The built-in-resistance in the production structure to off-set the random disturbances is of course brought about, by making appropriate changes in the factor inputs, e.g. by investing in irrigation facilities, assured and regular water supply can be obtained, and production can be made less vulnerable to droughts;

²⁸S.K. Mukhopadhyaya, Sources of Variation in Agricultural Productivity, The Macmillan Company of India Limited, 1976, p.56.

by adequate flood prevention measures, danger of floods can be averted; necessary provision for insecticides and pesticides, can provide protection against pests and insects. Similarly, knowledge about changes in cropping pattern in favour of agro-climatic conditions and increased cropping intensity if properly utilised can render output less sensitive to random fluctuations. But for all this to happen it is necessary that²⁹ farmers.—

- i. possess adequate knowledge about improved seeds, chemical fertilisers and new farm practices along with the knowledge of costs, yields and returns associated with these inputs.
- ii. are ready to undertake the risk and uncertainty attached to switching over from long established traditional practices to newer ones.
- iii. have the ability to make the necessary investment required for this purpose either from borrowings or from their own resources. It is only when all these conditions are met that changes in cropping intensity and cropping pattern occur which in turn provide growth and stability to agricultural production.

²⁹ Biplab Das Gupta, The New Agrarian Technology, The Macmillan Company India Limited, 1980, pp.239-256.

The limited change in cropping pattern that has taken place during 1965-66 the year when the bio-chemical technology was introduced in the State showed that the scope for introducing any change in the technology was limited by the subsistence nature of the farm economy.³⁰ Among the various factors which affected this inducement was the important role played by the knowledge factor. Studies³¹ have found that during the initial stage of introduction of HYV the knowledge of improved seeds and related inputs was not properly circulated among the farmers. Only a group of affluent farmers had access to this knowledge. Majority of the small farmers neither had any knowledge of the new technology nor of the various sources from where they could raise finances to undertake the investment required for this purpose. Gradually as the knowledge of the new technology was absorbed by the farmers their response to it increased, reflecting itself in changes in cropping pattern, changes in gross

irrigated area as percentage to gross cropped area, use of chemical fertilisers etc. (see Tables VI.8 and VI.9). These changes were more pronounced during the period 1974-75 to 1980-81 due to which contribution of TFP works out to be much higher during this period in comparison to the earlier periods i.e. 1960-61 to 1967-68 and 1967-68 to 1974-75.

Table VI.8 : Growth of Some Relevant Indicators in U.P.

Period	Index of cropping intensity	Index of percentage of gross irrigated area to gross cropped area	Index of use of chemical fertilisers
1960-61 to 1967-68	100.00	100.00	100.00
1967-68 to 1974-75	102.47	142.43	245.75
1974-75 to 1980-81	105.32	174.38	783.33

Years	Paddy	Wheat	Maize	Jowar	Bajra
1968-69	7.77	26.80	5.96	0.97	0.95
1974-75	32.20	67.41	1.45	-	4.50
1977-78	44.57	81.15	2.68	4.30	12.53

Source : A Fact Book on Agricultural Production, Steering Group on Agriculture, State Planning Commission, Uttar Pradesh, Lucknow, January 1980, p.36.

Table VI.8 and Table VI.9 show that but for irrigation, for all other indicators growth has been very fast during 1974-75 to 1980-81. Thus total factor productivity which acted as a negative source of growth during 1960-61 to 1967-68, turned out to be a positive contributor during 1967-68 to 1974-75. It became the chief contributor during 1974-75 to 1980-81 and pushed up the rate of growth of output to a level which is substantially higher compared to the rate of growth obtained during the two earlier periods.

2.2.2 Secondary Sector : Table VI.10 presents average compound growth rates of inputs and output in the secondary sector of the State. Absolute and relative contributions of sources of growth to the growth rate of sectoral output have been presented in Tables VI.11 and VI.12 respectively.

Source : Table VI.11.

It is evident from Table VI.10 that TFI in the secondary sector has grown at an average compound rate of 4.59 per cent per annum. It has, however, grown more fast during seventies as compared to sixties owing to the fast increase in labour input during the latter decade which seems to have offset the sharp decline in the rate of growth of capital input during the same period. Table also shows that after having declined during 1967-68 to 1974-75, TFI has again increased sharper during next six years, 1974-75 to 1980-81. Changes in the growth rates of labour and capital, account for such behaviour.

Table VI.11 shows that the decade 1960-61 to 1980-81 about fourth-fifth of the growth of real output came from increase in the quantities of labour and capital leaving about one-fifth as the contribution technological change or productivity growth. It is striking to note however that, the relative contribution of TFP (as well as its absolute contribution) declined sharp during seventies compared to the earlier decade. Labour's contribution has increased greatly and that of capital reduced to more than half in seventies, compared to the decade 1960-61 to 1970-71. While during

1960-61 to 1970-71, capital turned out to be the chief contributor to the growth of output, the place was taken away by labour during seventies.

Three period division of the reference period (1960-61 to 1980-81) brings out the pattern of growth of input, output and TFP in this sector more clearly.

During 1960-61 to 1967-68, the contribution of capital was about three times that of labour. TFI grew faster than real output, TFP played a negative role.

The period from 1967-68 to 1974-75 showed improvement in the situation. During this period TFP made a positive though very small contribution to growth of income in the secondary sector. About 50 per cent of growth during this period came from capital input. Relative contribution of labour worked out to be 40.94 per cent which is much higher compared to its contribution during 1960-61 to 1967-68.

The period from 1974-75 to 1980-81 showed a completely changed scene in comparison to the other two phases of economic growth. This period experienced a

moderate increase in the contribution of labour, a sharp decrease in the contribution of capital and fast increase in TFP, compared to the earlier period 1967-68 to 1974-75.

An insight into the structure of the secondary sector reveals that, the two major components of this sector viz. household manufacturing and construction are highly labour intensive. The household manufacturing sector utilises only small quantity of capital and production in this sector is carried out, using traditional methods. While the sector has its own importance regarding promotion of income and employment, it can not be expected to act as a leading sector for increasing productivity in the secondary sector. It is the large scale manufacturing sector, which by better use of labour and capital resources and changes in technology, can accelerate the pace of productivity. And it is this sector that has lagged behind during during 1960-61 to 1967-68³² explains, why TFP growth

³² During this period the two important industries namely sugar and textiles which accounted for bulk of the labour employed, in this sector were in bad shape. These industries had old and worrout machinery that needed replacement and modernisation. See, (i) Techno-Economic Survey of U.P., National Council of Applied Economics Research, 1965, pp.107-109.

Contd...

acted as a negative source of growth during this period.

The improvement in the situation during 1967-68 to 1974-75 is explained by changes in the structure of the manufacturing industries. During this period, the structure turned more in favour of industries producing capital goods and chemical products, using modern technology.³³ This appears to be one of the reasons that changed negative contribution of TFP during 1960-61 to 1967-68 into a positive contribution during 1967-68 to 1974-75.

It is to be noted that the positive though small contribution of TFP during this period is accompanied by a sharp increase in the contribution of labour and a decline in the contribution of capital in comparison to the period 1960-61 to 1967-68. Thus, while capital

still occupied the highest rank among the sources of growth in this sector, its importance with respect to labour declined as compared with the earlier period. The increase in labour input during this period both in factory establishments and in the household sector, causing a decline in capital input per unit of labour, perhaps resulted in better utilisation of capital input and thereby resulting in a positive contribution of TFP.

Similarly increase in the relative contribution of TFP during 1974-75 to 1980-81 accompanied by decline in relative contribution of capital, when viewed in the light of variations in the rates of growth of these two inputs over-time suggest, that during this period increasing labour input has cooperated with slowly increasing capital goods containing new technology in a better way compared to the earlier periods. In fact it implies that labour has become more efficient and has adjusted itself with changing technology.

2.2.3 Tertiary Sector : The tertiary or the service sector provides the infrastructure for the development of the commodity producing sectors of the economy.

While growth of this sector depends on the growth of the commodity producing sectors of the economy, a weak tertiary sector can also act as an impediment for the future growth of the commodity producing sectors and thus for the growth of the economy. For analysing the main sources of growth in the tertiary sector average compound growth rates of inputs and outputs have been presented in Table VI.13.

Table VI.13 : Average Growth Rates of Inputs and Output Tertiary Sector

Inputs / Outputs	1960-61	1960-61	1970-71	1960-61	1967-68	1974-75
	to 1980-81	to 1970-71	to 1980-81	to 1967-68	to 1974-75	to 1980-81
1. Labour	1.05	.16	1.95	.16	1.14	1.99

3. T F I	1.82	1.02	2.62	1.09	1.72	2.79
4. Output	3.30	3.20	3.40	2.41	3.16	4.52

Source : Row No. (1) Table IV.4.
 (2) Table V.5.
 (3) Appendix Table F.1.
 (4) Table II.3.

It is observed that during the period of two decades 1960-61 to 1980-81 TFI in this sector has increased at an average rate of 1.82 per cent per annum. Rate of growth of TFI is much faster in the latter decade compared

to the former decade. In fact growth rate of TFI revealed from the table^(VI.13) that increasing rate of labour input has been the major factor for pushing up the rate of growth of TFI during all the periods. Contributions of different sources to the growth rate of sectoral output have been presented in Tables VI.14 and VI.15.

Table VI.14 : Absolute Contribution of Various Sources to the Growth Rate of Output in the Tertiary Sector

Growth Sources Output	(Percentage Points)					
	1960-61 to 1980-81	1960-61 to 1970-71	1970-71 to 1980-81	1960-61 to 1967-68	1967-68 to 1974-75	1974-75 to 1980-81

Source : Table VI.14.

During the reference period of two decades, both labour and capital have contributed equally to the growth of output in the tertiary sector (Table VI.14). Together they made 55.16 per cent contribution, remaining 44.84 being contributed by technological change. Inter temporal comparison over the two decades shows (Table VI.15) that relative contribution of labour input has declined. This trend is accompanied by the declining trend in the relative contribution of technical change through time. Looking back at Table VI.13 it can be

easily seen that decline in the growth rate of capital input and fast increase in the rate of growth of labour input is the main factor behind this trend.

Studying the contributions of sources of growth during three sub-periods viz., 1960-61 to 1967-68, 1967-68 to 1974-75 and 1974-75 to 1980-81; it is found that conclusions remain broadly the same as above i.e. relative contribution of labour input has increased through time and that of capital, and technical change have declined. Thus failure to provide more capital per worker has been the major factor causing decline in the contribution of technological change or productivity growth in this sector.

2.3 Analysis of Sources of Growth - Embodied Technical Change

The analysis in the preceding section assumed technical change to be purely disembodied i.e., technology grows through time and enables same amount of labour and capital to produce more output. However, technical change is not purely disembodied; a part of it is embodied in labour and capital.³⁴

³⁴A. Heertje, op. cit, p.174.

While many theoretical models have been developed to account for the technical change,³⁵ working with embodied change is quite a cumbersome procedure especially for capital. During the process of growth more productive capital goods embodying latest technology are brought into the productive system. This improves average quality of the capital stock, depending upon its age structure (which depends itself on the rate at which new capital goods are brought into the system) and the rate at which technical progress improves the quality of the new capital goods. Since latter is one of the unknowns, empirical studies depend on trial and error methods to obtain the rate of embodied technical progress which gives the best fit for the function to be estimated.³⁶ To avoid these problems, capital here has been measured net at constant prices and the effect of changes in the productivity of capital are assumed to be reflected in the measure of the residual.

³⁵ R. Solow was the first economist to incorporate Technical change in the Cobb-Douglas Production Function. See, R.M. Solow, "Investment and Technical Progress" in Mathematical Methods in Social Sciences, K. Arrow, S. Karlin and P. Suppes (eds.), Stanford University Press, 1960, pp.89-104.

³⁶ A.P. Thirlwal, Growth and Development, op.cit, pp.70-71.

An attempt has, however, been made to account for the technical change embodied in labour input. The average quality of labour is greatly effected by changes in the educational level of the work force and changes in its sex-composition.³⁷ The index of labour input duly adjusted for these qualities was prepared in Chapter IV (Table IV.21). Due to non availability of sector-wise education income differentials, the quality adjustment could be made only on aggregative basis. Hence embodied analysis of sources of growth has also been undertaken on the aggregative basis. Total factor input obtained by combining quality adjusted index of labour input with capital and land inputs (using factor share as weights) has been presented in Table VI.16. Average compound growth rates of total factor input (quality adjusted) along with growth rates of its different components have been presented in Table VI.17.

³⁷ This is not of course the exhaustive list of all the factors that affect the quality of labour input in any economy during a period of time. Besides these, there are a host of other factors like changes in the health level of the work force, changes in the occupational shifts, changes in the length of hour worked etc. which effect the quality of labour input.

Table VI.16 : Total Factor Input (Adjusted)
and Its Main Components

Years	Labour (quality adjusted)	Capital	Land	T F I

7. Output	2.71	2.54	2.88

Source : Tables VI.2, VI.5 and IV.21.

It is evident that except employment, growth rates of all other inputs have declined during the decade 1970-71 to 1980-81 as compared to the decade 1960-61 to 1970-71 (Table VI.6). It is interesting to note, however, that despite lower growth rates, TFI during the latter decade has grown much faster compared to its growth during the earlier decade. Thus the increase in the rate of employment and increase in the percentage

shares of both labour and capital during the end of seventies, seem to have more than offset the effect of decline in growth rates of inputs. Absolute and Relative contributions of sources of growth to the growth rate of output have been presented in Table VI.18.

Table VI.18 : Contributions of Different Sources to the Growth Rate of Output

Sources of growth Output	Absolute Contribution			Relative Contribution		
	1960-61 to 1980-81	1960-61 to 1970-71	1970-71 to 1980-81	1960-61 to 1980-81	1960-61 to 1970-71	1970-71 to 1980-81
1. Employment	.99	.64	1.36	36.53	25.20	47.22
2. Quality of labour due to increased education and changing sex-composition	.64	.88	.38	21.07	34.65	13.19
(1+2) 3. Labour	1.63	1.52	1.74	60.15	59.85	60.42
4. Capital	.85	.87	.80	31.37	34.66	27.77
5. Land	.09	.12	.09	3.32	4.72	3.13
6. T F I (adjusted)	2.57	2.51	2.63	94.84	98.82	91.32
7. T F P	.14	.03	.25	5.16	1.18	8.68
8. Output	2.71	2.54	2.88	100.00	100.00	100.00

Source : Table VI.17.

Adjustment for quality of labour shows, that during the two decades i.e. 1960-61 to 1980-81 as well as during each of the decade, both in absolute and in relative terms, highest contribution came from labour input. Over the two decades 1960-61 to 1980-81, quantity and quality of labour input is found to have contributed 60.15 per cent of the growth of output. Quality of labour has made a contribution of 23.62 per cent towards the output growth. It is of concern however, that both in absolute and in relative terms contribution of quality has reduced during seventies as compared to sixties; although its reduced effect has been offset by the faster growth in employment during 1970-71 to 1980-81 as compared to the earlier decade.³⁸

Accounting for labour embodied technical change has reduced the relative contribution of TFP from 28.42 per cent (Table VI.3) to 5.16 per cent. This shows 82.05

³⁸ Despite the decline in the relative contribution of labour quality during 1970-71 to 1980-81 as compared to 1960-61 to 1970-71, relative contribution of labour input (adjusted for quality change has not declined during the latter decade as compared to the earlier) implying that reduced effect of labour quality has been more than made up by the faster growth of labour quantity.

per cent of technical change during 1960-61 to 1980-81 was labour embodied, remaining 17.95 per cent was either embodied in capital or acted in a disembodied way. During 1960-61 to 1970-71, 96.70 per cent of the technical change was labour embodied while in the latter decade this percentage reduced to 60.32 only i.e. 39.68 per cent of technical change during 1970-71 to 1980-81 was either embodied in capital or acted in a disembodied way coming from such sources as changes in resource-shifts, economies of scale, changes in the form of business organisation, advances in knowledge etc.

2.4 Conclusions

Main conclusions emerging from the analysis in this chapter can now be summarised as:

1. During the two decades 1960-61 to 1980-81 traditionally measured inputs contributed a substantial part (71.59 per cent) of the growth of real income in the economy.
2. During twenty years considered, increase in the quantity of labour has made the largest contribution to the growth of real output in the economy. Contributions of capital and land come next in sequence.

3. Over the two decades 1960-61 to 1980-81 total factor productivity or technological progress has grown at an average compound rate of 0.77 per cent per annum contributing 28.41 per cent of the growth of real output in the economy.

4. The rate of technological progress has declined during seventies as compared to sixties. However adoption of a three period division of the period (1960-61 to 1980-81), according to different phases of growth observed in the economy reveals that although technological progress grew at a negative rate during the early phase, its rate has improved since 1967-68 and has been significantly faster during latter part of seventies, 1974-75 to 1980-81.

5. Decadal comparison reveals improvement in the rate of growth of total factor productivity in the primary sector during seventies as compared to sixties. Reverse to this, however, happened in the tertiary and secondary sectors.

6. Both primary and the secondary sectors, reveal negative contribution of technological change during

the initial phase 1960-61 to 1967-68, and faster growth during 1974-75 to 1980-81. However, technological progress has been faster in the primary sector than in the secondary.

7. In the tertiary sector although rate of technological progress shows constant improvement, its relative contribution is found to have declined during latter periods i.e. 1967-68 to 1974-75 and 1974-75 to 1980-81 compared to the early phase 1960-61 to 1967-68.

8. Intra sectoral comparison of inputs and output for the three period division of the study period, suggests that variation in rates of growth of inputs have resulted in changes in their combined efficiency.

9. Analysis with embodied technical change, with improvements in the quality of labour due to increased education and changing sex-composition of the work force, counted with growth in factor quantities, reveals that :

1. Over the two decades considered as a whole, 23.62 per cent of the growth real income represents contribution of labour quality.

- ii. Absolute and relative contributions of labour quality have declined during seventies as compared to sixties, though this declining effect is found to have been compensated by the growth of employment, so that contribution of labour does not decline but shows a marginal increase in seventies as compared to sixties.

Table F.1 : Indices of Total Factor Input
in the Three Sectors

Years	Primary sector	Secondary sector	Tertiary sector
1960-61	100.00	100.00	100.00

Chapter VII

CONCLUSIONS

The present chapter recapitulates main findings of the exercise on measurement of the sources of growth of the economy of Uttar Pradesh contained in the previous chapters; and attempts to bring out implications of these findings for the pattern of growth and resource-use-efficiency in the growth process of the State.

For the purpose of analysis two alternative periodisations were adopted. First, a decadal comparison was undertaken. Second, the analysis was undertaken by dividing the study period into three parts 1960-61 to 1967-68; 1967-68 to 1974-75 and 1974-75 to 1980-81. The latter periodisation highlighted three different phases of growth of the economy — (i) very slow growth, (ii) fluctuating but moderately high growth, (iii) high and stable growth; and seemed to correspond to some major changes occurring in the economy such as the introduction of new agricultural technology in

1966 and significantly high and stable growth recorded by all the three broad sectors in the economy viz, primary, secondary and tertiary since the mid seventies. The analysis based on this periodisation, therefore, appeared more appropriate for drawing implication of the findings of the study.

1. Growth of Real Income

(i) During the twenty years period 1960-61 to 1980-81, the real aggregate income of the economy of Uttar Pradesh has grown at a rate of 2.71 per cent per annum. It has, however, experienced varying growth rates during different parts of this period. If the two decades covered in the study are considered separately, it is found that the decade 1960-61 to 1970-71 experienced a growth rate of 2.54 per cent per annum and the next decade, 1970-71 to 1980-81, of 2.88 per cent per annum.

(ii) On a closer look one finds three distinct phases in the entire period. During the period 1960-61 to 1967-68 the State economy experienced a very slow growth rate. There was a gradual improvement in the next seven years. But, a real break-through seems to

have taken place during 1974-75 to 1980-81. This period experienced a rate of growth of 4.97 per cent as compared to 2.19 per cent during 1960-61 to 1967-68 and 1.34 per cent during 1967-68 to 1974-75.

2. Sectoral Growth

(i) During the entire period of the two decades, the primary, secondary and tertiary sectors experienced growth at average annual compound rates of 1.77, 5.78 and 3.30 per cent respectively. While both primary and the tertiary sectors, improved their growth rates during 1970-71 to 1980-81 in comparison to the earlier decade i.e. 1960-61 to 1970-71, growth rate deteriorated in the secondary sector.

(ii) All along the twenty years, average growth rate of the State economy has remained dominated by the growth in the primary sector, due obviously for the fact that this sector contributes largest share of the State income. Almost stagnant primary sector, resulted in the sluggish growth of the State economy during 1960-61 to 1967-68. Improved performance of the primary sector after 1967-68 and especially after

1974-75 is reflected in the better performance of the State economy during these periods.

3. Income Structure

During 1970-71 to 1980-81, the economy has experienced a gradual shift in the sectoral incomes with percentage share of the primary sector declining by 4.99 per centage points as compared to its percentage share during 1960-61 to 1970-71. While a gradual decline in the percentage share of the primary sector is a natural corollary of development, the fact that this has gone in favour of the tertiary sector, instead of secondary, has some serious implications for the economy. Increase in the percentage share of the service sector, consequent upon the decline in the share of the commodity producing sector (primary and secondary) is likely to have added to the inflationary pressure in the economy.

4. Functional Classification of Income

The exercise on functional break-down of State income among the primary factors -- land, labour and capital has some interesting findings to offer.

(i) There has been no substantial change in the percentage share of labour over the period of twenty years, confirming the hypothesis of 'constant labour share' for the State economy.

(ii) Percentage share of capital shows a mildly increasing trend and that of land a correspondingly declining one, suggesting that the nature of technical change has been land augmenting.

(iii) The functional distribution of State income by sectors, shows that by and large, all the three sectors viz. primary, secondary and tertiary support the constant labour share hypothesis. However, secondary and the tertiary sectors, reveal a mildly increasing trend in the percentage share of labour, which is more pronounced in the secondary sector than in the tertiary sector. In the case of the primary sector, percentage share of labour has been almost static.

(iv) Share of labour, in the income of the primary sector is relatively small, in comparison to its share in the secondary and tertiary sectors. This, when viewed in the light of the fact that primary sector accounts for the largest percentage of total employment,

reflects the low level of productivity of labour in this sector. A gradual decline, which the primary sector has undergone in terms of its percentage share of employment, therefore portends an encouraging sign.

5. Labour Input

(i) Labour input in the State economy measured as the increase in the working force, registered a growth of 30.34 percentage during the study period, growing annually at an average compound rate of 1.33 per cent.

(ii) Of the two components of labour input - males and females, the latter showed a decline during the two decades, and thus checked a faster growth of labour input in the economy. It is important to note however, that sex-composition of the work force which moved against females during 1960-61 to 1970-71 has taken a positive turn in their favour during 1970-71 to 1980-81. Female labour input which during sixties grew at a rate of -3.18 per cent per annum, recorded a positive growth of .13 per cent per annum during the seventies. Consequently, growth in labour input has been faster during the latter decade as compared to the earlier one.

(iii) The sectoral composition of labour input revealed a moderate shift away from the primary sector in favour of secondary and the tertiary sectors. But that a part of this shift has gone in favour of the tertiary sector, indicates failure of the secondary sector to provide increased opportunities for employment. It is, however, noted that while during 1960-61 to 1970-71 fastest growth in labour input occurred in the primary sector; during seventies, fastest growth has been recorded in the secondary sector.

(iv) During the study period of two decades quality of labour input measured in terms education and sex-composition of the work force has increased at a rate of 1.03 per cent per annum. Rate of growth of quality change has however declined during seventies compared to the period 1960-61 to 1970-71. If we add qualitative changes to the quantitative increase, growth of labour input during the period of two decades has been of the order of 59.93 per cent. Thus 43.88 per cent of the measured growth of labour input is accounted for by the effect of qualitative changes in labour input. However, importance of these factors in raising the growth of labour input has decreased with time as revealed by its decreasing effect during seventies.

6. Capital Input

(i) Capital experienced the fastest growth among inputs during the study period 1960-61 to 1980-81. Measured at constant 1970-71 prices, it increased at a rate of 4.45 per cent per annum. Its rate of growth declined during the latter decade in comparison to the earlier one.

(ii) Capital input in the three sectors primary, secondary and tertiary grew at annual rates of 3.09, 9.45 and 3.72 per cent respectively. In all the three sectors growth of capital input declined during 1970-71 to 1980-81 in comparison to 1960-61 to 1970-71. A noticeable feature of the growth of capital input has been that, while during the first half of the study period highest growth of capital input occurred in the secondary sector, this sector also stood first in terms of decline in growth rates of capital input during the latter decade.

(iii) In terms of its sectoral composition, secondary sector had the smallest percentage of total capital input during the entire period of twenty years under reference. 93 per cent of the total capital input

during 1960-61 to 1980-81 represented shares of primary and the tertiary sectors, both sharing almost equally. However, secondary sector improved its percentage share in the total capital input during seventies, sharing about one-fourth of the total capital input used in production in the economy, compared to a 6 per cent share during sixties. Percentage shares of the primary and tertiary sectors declined during 1970-71 to 1980-81. While during sixties the tertiary sector accounted for the largest percentage in capital input, during seventies it was the primary sector which acquired the largest share. These changes in percentage share of the sectors in total capital input, reflect the importance placed on growth of these sectors during different plans. Larger shares of the tertiary and primary sectors during 1960-61 to 1970-71, show the importance placed on the development of infrastructure and agriculture. Growing share of the secondary sector reflects a shift from agriculture and infrastructure to the development of industrial sector in the latter years.

7. Land Input

(i) During 1960-61 to 1980-81, land input in the economy shows a marginal growth of 0.29 per cent per annum. Rate of growth during seventies is lower compared to sixties. Decline in the rate of growth of land input with time suggest that the possibilities of increasing land, one of the basic input for production, are becoming increasingly limited.

8. Total Factor Input

(i) Over the period of two decades 1960-61 to 1980-81, combined input of land, labour and capital or the total factor input has grown at a rate of 1.94 per cent per annum. The growth rate has accelerated with time being higher in the latter decade compared to the earlier. Labour input has been the dominant component of this growth, all along, the twenty years period. When qualitative improvements are also counted as a part of growth in factor quantity, total factor input registers a growth of 68.03 per cent or 2.47 per cent per annum.

(ii) Pattern of growth of total factor inputs, however, varied among sectors. While total factor input has been increasing in all the three sectors, in case of the primary sector, its rate of growth has been slower during 1970-71 to 1980-81 as compared to 1960-61 to 1970-71, while both in the secondary and the tertiary sectors, total factor input has grown faster during seventies as compared to sixties.

9. Contributions of Sources of Growth

(i) During the entire period of two decades 1960-61 to 1980-81 increase in the quantity of traditional factor inputs, explains 71.59 per cent of the increase in output. Most important source of growth has been labour with an average contribution of 36.53 per cent. Next important source has been capital with an average contribution of 31.37 per cent. Importance of land in contributing to the growth of the State economy has turned out to be the lowest.

(ii.) When quality changes are also counted with factor quantity, and are not assumed to be included into the residual effect, termed as technical change,

contribution of labour rises to 62.36 per cent and that of technological change drops to 5.16 per cent. 23.62 per cent of the growth of output during 1960-61 to 1980-81, represents contribution of labour quality.

(iii) The relative importance of various sources has, however, been different among the three sectors. Labour has been the major source of growth in the primary sector, and capital in the secondary sector. In the tertiary sector both labour and capital are found to have been equally important.

(iv) The study finds that over the period of two decades the economy of Uttar Pradesh experienced disembodied technological progress at a rate of 0.77 per cent per annum, contributing 28.41 per cent of the growth of real income in the economy. In comparison to the rate of growth of capital (4.45 per cent) during this period, the rate of technological progress is obviously very slow, indicating the slow rate of absorption of technology in the economy. A further decline in this rate during seventies as compared to sixties as revealed by decadal comparison, is all the more disquieting.

(v) However, the rate of technological progress and its relative contribution to the process of growth of the economy is found to be continuously improving. If we look at the trend by dividing the entire 20 years period into three sub-periods as indicated earlier, it is seen that from a negative rate of $-.29$ per cent during the initial phase 1960-61 to 1967-68, the rate of technological progress improved to $.20$ per cent during the next phase 1967-68 to 1974-75 and jumped to 2.71 per cent during 1974-75 to 1980-81.

(vi) With the introduction of new agricultural technology in 1966, a gradual improvement is seen to have taken place in the productivity of the economy after 1967-68. A faster growth of total factor productivity during latter seventies also seems quite consistent with the available facts about more stable and faster growth in agriculture and manufacturing sectors resulting from (i) a wider application of new agricultural technology, and (ii) changes in the structure of manufacturing industries in favour of capital goods producing industries, which are known to be the carriers of technological change.

(vii) The pattern of negative technological progress during 1960-61 to 1967-68, a gradual improvement in it after 1967-68 and its relative faster growth during 1974-75 to 1980-81 are clearly observed for the primary and secondary sectors. The increase however, has been faster in the primary sector, so much so, that technical change is found to have made a greater contribution than increase in factor quantities in this sector, during 1974-75 to 1980-81. In the tertiary sector, however, relative contribution of technological change is found to have declines since 1967-68.

(viii) A general conclusion emerging from these trends is that the rate of growth of technological progress in the State economy has been determined by the productivity performance of its two broad sectors viz. primary and the secondary. Both primary and the secondary sector having revealed a negative rate of total factor productivity during 1960-61 to 1967-68, the technological progress was negative in the economy. With moderate growth of productivity revealed by these two sectors during 1967-68 to 1974-75, a gradual improvement towards a positive growth of total factor productivity occurred in the aggregate also. With the two sectors

experiencing higher productivity growth during 1974-75 to 1980-81, technological progress turned out to be significantly higher in the economy.

(ix) The tertiary sector is found to have been relatively less important in influencing the rate of technological change in the economy. Despite higher productivity in this sector during 1960-61 to 1967-68, the rate of growth of total factor productivity in the economy turned out to be negative.

10. Conclusion

The above highlights of the study of the relative importance of various sources in the process of economic growth of the State economy bring out some interesting implications.

1. As could be expected, the study shows that during early stages of economic development technological change was a relatively less important source; its importance grew with the growth of the economy.

2. There seems to have occurred a significant change in the efficiency of resource-use in the economy. Negative rate of technological change during 1960-61 to

1967-68 shows decline in the efficiency of resource-use. This may be due to the fact that a part of the resources were still in the process of being converted into productive assets and were not fully utilised during the period. Although large investments were made in the development of infrastructure and various projects in the initial phase, the quantity and quality of labour input was probably inadequate to complement these inputs. In the latter period, better utilisation of created infrastructure, completion of development projects such as irrigation and power and use of necessary quantity and quality of labour input have led to a rise in the efficiency of resource-use. This change has resulted both in the higher rates of growth of real income and a larger contribution of technological change to the growth of output.

Increasing use of labour than of capital as a source of higher productivity and growth, which is observed in the aggregate is, however, not necessarily true in each sector. In case of the tertiary sector, increasing growth rate of labour accompanied by lower rates of capital during 1974-75 to 1980-81, compared

to the earlier period i.e. 1967-68 to 1974-75, have reduced the relative contribution of technological change. Here, the increasing numbers, had to work with smaller amount of capital per head than before; thus reducing productivity. In the case of the primary sector, decline in the growth rate of both labour and capital and increase in the growth rate of land input during 1974-75 to 1980-81 in comparison to the rates experienced by these inputs during 1967-68 to 1974-75 have resulted in greater contribution of technological change, leading to higher growth of output.

In case of the secondary sector, increase in the rate of growth of labour and decreases in the rate of growth of capital during 1974-75 to 1980-81, compared to the earlier periods, are found to be associated with a relatively larger contribution of technological change. It shows in fact, that increasing labour has more efficiently combined with the capital, which has, though increased at a slower rate than in the earlier periods. Thus while during 1974-75 to 1980-81 both primary and the secondary sectors were able to raise growth and productivity by their efficient resources utilisation, the tertiary sector failed to do so.

3. Inter-sectoral productivity trends and related rates of labour input suggest that structural shift in employment noticed during the latter seventies has been an important source of increasing efficiency of factor inputs in the primary and secondary sectors which together have resulted in the increased efficiency of factor inputs at the aggregate level, even though, productivity declined in the tertiary sector.

4. Changes in the rates of growth of labour and capital inputs and associated direction of technical change, suggests that the nature of technical change experienced by the State economy has been capital augmenting and labour intensive. In the primary sector, where technical change is found to have occurred to a perceptible extent, it has been land augmenting and capital and labour substituting. Thus, nature of technical change is found to have been quite consistent with the factor endowments of the labour abundant and capital-land scarce economy.

5. The observed pattern of technical change and the process of economic growth of the State over the

sub-periods seem to offer two alternative hypothesis. First, faster growth of real income and productivity experienced during the latter years are the outcome of economies of large scale production obtained by use of greater factor quantities. Alternatively, the move towards optimal use of basic factor inputs by way of factor substitution has tended to speed up the growth of real income and productivity during the latter years.

The general evidence available about the size structure of production units in the economy does not lend much support to the 'economy of scale' hypothesis. For, the production structure of the two broad sector viz. agriculture and industry, which shape growth of income and productivity in the economy, have shown signs of getting more and more decentralised with time. In agriculture, operational holdings with less than one hectare of cultivable area have increased by 12.6 per cent during the two agricultural Censuses 1970-71 and 1975-76. During the same period large agricultural holdings with 10 or more hectares of area declined by 23.2 per cent.¹ Similarly the production structure of

¹Uttar Pradesh Ki Arthik Sneeeksha (Hindi), Directorate of Economics and Statistics, State Planning Institute, U.P., 1979-80, pp.25-26.

the manufacturing sector is getting more and more ... dominated by small scale units. During 1960-61 to 1979-80, the number of small scale units registered with Directorate of Industries increased from 3107 to 47943² i.e. 1443 per cent. During the same period number of registered factories in the State increased from 2599 in 1960-61 to 5540 in 1980-81³ i.e. 113 per cent. Average number of employment per factory for large and medium scale units in the State has also registered a declines from 407 to 315 during 1960-61 to 1980-81.⁴

Thus the average size of production units have shown a declining tendency during the periods, which goes to disfavour the hypothesis that improvement in resource-use efficiency is attributable to the economies of large scale production.

It, therefore, appears that complementarity of factor inputs which seems to have moved towards optimality has been the decisive factor for the magnitude

²Five Year Plan, Draft Annual Plan 1981-82 (Review), U.P, Vol.II, p.86.

^{3&4}Annual Survey of Industries, U.P, Directorate of Economics and Statistics, State Planning Institute, U.P.

and direction of technical change during the latter years. The inefficient factor combination during the earlier phase with more capital and less labour in the aggregate and in their unfavourable combination at the sectoral level, led to a low level of efficiency of resource use.

However, in due course of time, experience and expertise has improved⁵ labour skill. Capital also seems to have been modified to suit the existing requirement. With these changes taking place factor inputs have turned out more complementary to each other and their combined efficiency has improved.

A significant role in this regard has of course been played by factors such as easy and regular availability of necessary quantity and quality of intermediate inputs and improved infrastructure, especially the transport and communication net work and market expansion. Increasingly larger allocations

⁵Although relative contribution of labour quality is found to have declined during seventies as compared to sixties in our study, this is not to mean that labour quality is in fact deteriorating. Though the number of literates in the work force might not have increased as fast during seventies as during sixties yet even by experience and effect of education in the population; the quality of labour is sure to have increased with time.

from plan to plan on the development of basic infrastructure required for production such as power, irrigation, transport and communication etc. reveal that in fact the external economies generated by these factors have increased the scope of substitution between the factor inputs by turning them more complementary to each other, and have increased each other productivity.
